peated formal and informal evaluations. Unfortunately, these evaluation reports have not themselves been completely successful in that application of their findings has often led to serious social and political problems (31–33). Possibly this is because the original practices that were demonstrated to be effective were only incompletely duplicated in subsequent situations. In addition, evaluation findings have been ignored by some planners and administrators who were either unaware of them or did not accept them (34). Appropriate use of evaluation study results, therefore, has not been overwhelmingly demonstrated in this instance.

Another possible success story of program evaluation has been the demonstration of the effect of community mental health centers in decreasing the number of state hospital patients in the United States (35, p. 17). Demonstration of the effectiveness of the centers and the consequent general acceptance of the center concept by planners and administrators has been clouded by cutbacks in funding for the centers. These cutbacks might even possibly lead to the centers' eventual demise. Interestingly, funding cutbacks are sometimes explained as resulting from the centers' demonstrated success and at other times as resulting from the centers' demonstrated lack of success. An official publication of the National Institute of Mental Health (36) pointed out that the remarkable decline in number of state hospital patients began before the centers were established, and other reporters looking at the same data (37) questioned whether they really show effectiveness of mental health centers at all.

The failures of good program evaluation studies to have any impact on subsequent programs are far more numerous than the successes. Fairweather and associates (38) reported a number of studies showing the effectiveness of moving state hospital patients as a group into the community in preventing rehospitalization and relapse. However, they were unable to induce psychiatric hospitals in the United States to institute this innovation in spite of the fact that they offered a variety of encouragements and free consultations (39).

Pasamanick and associates (40) showed how the use of visiting nurses could alleviate the need for most mental hospitalization and thereby save money and lower patient morbidity. However, their program has apparently not been tried as an alternative on a substantial scale anywhere else in the country.

Negative evaluation studies, i.e., studies showing that a program does not accomplish its goals, seem almost never to have any impact on the particular program studied or on the field in general. Programs that have been negatively evaluated and yet have not generally changed include suicide prevention centers (41, 42), crisis intervention programs (43), social casework services (44), mental health education (45), and vocational rehabilitation of ex-mental hospital patients (46).

A situation very analogous to a formal negative evaluation and suggestive of the problems in implementing negative evaluation findings was seen in the nursing home scandal in New York State. Practically every public official and citizens' group that examined this situation agreed that conditions in many nursing homes in New York State were terrible (47, 48), but, despite the best efforts of the state government, it has not been possible several years later to bring about change (49, 50). It seems quite likely that other serious efforts by government to close or change mental health agencies found through formal evaluation studies to be performing inadequately will also be met with injunctions, lawsuits, and public countercharges.

A very striking aspect of the contemporary mental health scene is that evaluation studies so far have been limited to minor programs and fairly minor aspects of major programs. Major service programs that eat up large sums of money and on whose financial and political health many professional careers depend have never been evaluated; apparently, no efforts are under way to do so.

For example, the community mental health center movement has been in existence long enough and there is a sufficient number of mental health centers that major evaluation studies of centers as a whole and of each of the "essential elements" of a center ought to be possible. Almost none seems to have been reported, however. The research grant program of the National Institute of Mental Health has never been seriously evaluated either, in spite of the great hopes repeatedly expressed for it and the millions of dollars that have been disbursed through it. In addition, few of the various forms of psychiatric treatment have been evaluated, and these only on a very small scale and to a limited degree. There is still no generally used or accepted information available about which forms of psychiatric treatment, if any, are effective with which types of patients. There seems to be little clamor for evaluation in these areas, and the programs go on very well without it.

An observer might be led to the conclusion that top-level policy makers and professional leaders are concerned with evaluating only those programs which can be easily dispensed with. Large-scale programs are too serious a matter to be left to evaluators. When governmental or quasigovernmental inspection or evaluation of large-scale expensive programs has been attempted, it has not been uncommon for such evaluation activities to be seriously underfunded for the magnitude of the job involved and, sometimes, for the groups being evaluated to exert undue influence in one way or another over the evaluators (51–55).

Thus, despite the great hopes for evaluation and much lip service given to its importance, it seems that so far evaluation has accomplished little and that there is no sign of a future change in course.

PROMISE AND PERFORMANCE

There are several reasons for the disparity between the great promise offered in theory by evaluation and

the actual performance. When taken seriously, evaluation studies represent a major threat not only to professional careers but also to the stability of highly cherished beliefs and world views. The possible effects of a strongly negative evaluation on professionals include a change in employment and, possibly, career as well as a need to discard long-held theories of behavior without the immediate prospect of satisfactory substitute theories. What are we left with when a therapeutic procedure that simply *has* to work because all of our theory tells us it will turns out not to work? If we cannot discredit the evaluation or sharply limit its generalizability, we have a void in our framework for understanding the world.

The most comfortable solution to this stress is to ignore the meaning of the evaluation or, better still, never to do an evaluation. The history of any area of intellectual study shows repeated instances of man's capacity for self-delusion and for ignoring theoretically inconsistent and therefore uncomfortable facts (56, 57).

Even individuals who are not emotionally or professionally tied to a particular program or point of view are difficult to persuade by means of evaluation studies. Most of these studies are complicated, and their interpretation depends on sophisticated statistical and epidemiological techniques. Thus they are neither easy to understand nor easy to explain. Furthermore, when the evaluated program is dear to professionally competent individuals, they almost always attack the evaluation study on technical, methodological grounds. The battle between this group and those who defend the study soon becomes understandable only to a small group of experts.

Controversy surrounding the "Coleman report" (58) and the University Group Diabetes Program (UGDP) study (59) are good examples of this kind of battle. The former was an investigation of the effects of school segregation on school performance. Almost 10 years after its completion and after the publication of perhaps hundreds of articles and several books devoted to its examination, it is still not clear how reliable, valid, or generalizable the original study was. The UGDP study of the effects of oral antidiabetic drugs, which involved a number of major medical centers, has required several reanalyses of the data and is still mired in controversy. It may be "settled" in court. In cases such as these, in which experts cannot agree about the meaning of an evaluation study, how can a political leader or intelligent citizen be expected to make up his or her mind?

There are several other reasons why evaluation studies can never have more than a slight impact on the development of services. The budgeting of public agencies (in the current situation, most private and voluntary agencies actually depend in large part upon public support) is very much a political process. A budget allocation is usually the expression of pressures from a wide variety of sources funneling into "the final common pathway" of a monetary appropriation (60). All sorts of groups (e.g., professionals in the program, clients, local citizens, and businessmen trading with the agency) have vested interests in the well-being of an agency and the magnitude of its programs. The results of an evaluation study—even when clear-cut—can be but one minor pressure in the decision-making process. Even then, the evaluation study will have an effect only if some person or group in a position of power wishes to make use of the results. Evaluation studies obviously do not speak for themselves—their results must be disseminated somehow. Evaluators are in no political position to act as advocates for their studies because if they did so they would not likely have an opportunity to be evaluators again. If evaluation studies can only be a minor factor when results are clear-cut, how much less effective are they likely to be when results are controversial or not easily understood?

It is often assumed that even though citizens and political leaders may not easily understand or react to evaluation studies, the professionals whose work is under scrutiny will surely do so. The assumption is that all that needs to be done to improve professionals' work is to inform them of poor results. Many programs involving immediate feedback of evaluation results to administrators and clinicians are based on this assumption (61). Systematic evaluation (as contrasted with uncontrolled studies or testimonials) of the effectiveness of this approach seems lacking. Even in principle there is a question about how effective this process could be. What is the incentive for a professional to respond to a negative evaluation?

Although professional ethics and pride in our work are presumably encouragements to all of us to do the best we can and to change our ways when a study shows we are being ineffective, we are all under many strong pressures to keep doing things the way we have been doing them.

When the results of a negative evaluation study become known outside of an agency or profession, what is the incentive to the political leader or the private citizen to urge the agency to improve? No more than a small fraction of the total expenditure of tax funds is going to the agency; if a portion of those funds is being wasted, how much of a loss is it to any individual taxpayer? It seems naive in view of all that is known about political behavior to expect that evaluation studies are going to be a force leading to major improvement.

HAZARDS OF OVERENTHUSIASM

If evaluation studies are not the panacea that we have been told they are, what is the harm in describing them enthusiastically or expressing unrealistic hopes as fact? A good deal of harm can result from this kind of misguided enthusiasm.

The mental health fields have been beset by a series of fads in the last few years to the point where profes-

sional leaders seem to be rapidly losing credibility with politicians. Where once it took no more than a brief appearance before a legislative committee to open the funding floodgates, budgetary requests from mental health service agencies are clearly being examined very carefully now and being cut back without hesitation. In part this seems to be because programs that were recommended enthusiastically have turned out not to live up to their promise. It would be unfortunate to add program evaluation to this group.

Program evaluation costs money—when properly done, a great deal of money. Five to ten percent of the budget of a service program is sometimes talked about as a realistic amount to be devoted to evaluation. This amount is perhaps sufficient for a management information system but certainly not for an adequate evaluation. In a relatively small program, an evaluation unit can cost as much as the service program itself (61). To attempt to fund a large number of evaluation studies inadequately not only serves to waste much of the funds but is likely to prevent any studies from receiving enough funds to accomplish anything at all.

Finally, there is the important problem of a shortage of trained evaluators. If evaluation is to consist of more than simply collecting anecdotes from satisfied patients, evaluators must be trained in a wide variety of epidemiological, statistical, sociological, and administrative skills (62, 63). There are few training programs preparing individuals to carry out this work. There will not be a sufficient number of trained evaluators for many years to come to do evaluation work on the scale that has been talked about.

APPROPRIATE EVALUATIONS

In light of the difficulties mentioned here, when should evaluation be done? Obviously an evaluation study is worthwhile only when there is a likelihood or at least a good possibility that it will have an impact on the program evaluated and others like that program. Therefore, evaluation should be carried out only in a relatively small number of programs that are carefully selected (64). Each such program should be representative in all essential aspects of a general class so that results can be applied to a whole group of similar projects. The program should be easily describable so that it will be possible to replicate it without missing essential elements.

The program should be in its early stages or at least not so politically entrenched that a negative finding can be ignored with impunity. The program must be sufficiently malleable to make improvement possible.

The program should have goals that are related to the service it provides and that everyday observations suggest are likely to be attainable. An example of the disregard of this concept seems to be the suicide prevention centers, which contact only a small fraction of the individuals in the community at risk of suicide and which actually seem to be crisis counseling centers. It is not surprising, then, that suicide prevention centers have little or no impact on suicide rates in the communities they serve. Were the goals of these agencies more appropriately stated, their evaluations would likely not be so negative.

Finally, the evaluation should be designed and carried out in such a way that it is understandable to the political leaders and the citizens who will have to act in support of its findings. The study should be well known to them and have their support well before research begins.

CONCLUSIONS

If the current widespread, unquestioning enthusiasm for evaluation continues unchecked, history suggests that evaluation will go the way of several other recent fads in mental health and social welfare services. Enthusiasm will reach a crescendo of excitement, then interest will simply fade away, and evaluation will never have been properly tested or appreciated as a method of program improvement. To save it from this fate it is necessary to set limits on what is attempted in the name of evaluation and to err on the side of caution in predicting how useful evaluation studies will be. Program evaluation is potentially too important to be left to an unplanned demise.

Cancer, Emotions, and Mental Illness: The Present State of Understanding

BY FRIDA G. SURAWICZ, M.D., DENNIS R. BRIGHTWELL, M.D., WILLIAM D. WEITZEL, M.D., AND EKKEHARD OTHMER, M.D., PH.D.

The authors review recent and current literature on the relationship between psychological factors and cancer. They discuss the roles of predisposing personality patterns and emotional stress in the development, site, and course of cancer; the influence of awareness of terminal illness on the behavior of cancer patients; and the management of psychiatric symptoms in these patients.

THE LATTER HALF of the nineteenth century brought important progress in the discovery of the etiology and more accurate diagnosis of many somatic diseases. This progress resulted in an increased focus on cause-effect relationships and specific organ pathology. Twentieth-century medicine has been influenced by the impact of psychoanalytic thinking and by the metamorphosis of psychiatry from neurology's half-sibling into a separate and distinct medical speciality.

The coexistence of cancer and emotional distress has been noted by physicians for more than a century (1). Whether this association is described at length and in detail or only fleetingly mentioned seems to depend to some degree on whether the clinician regards the body and mind as a whole or as a dichotomy. Psychiatry's increased stature within medicine and its widened data base have reawakened awareness of body-mind unity. Regrettably, this has sometimes led to excesses in the interpretation of causative factors for somatic disorders, including cancer.

The medical literature of the 1950s and 1960s abounds with papers describing cancer as yet another psychosomatic disease, either precipitated by arrested personality development or preceded by specific emotional distress (2–11). In retrospect, one cannot help but feel that insult was added to injury by suggesting to cancer patients that immature personality development or a real or symbolic loss precipitated their malignant illness.

More recent literature has focused on rehabilitation for people with chronic or terminal diseases through improved adaptation to the emotional distress that accompanies such illnesses. Emotional distress in this conceptualization is viewed more as a response to than as a cause of illness (12–19). Preliminary studies in endocrinology and immunology are rekindling interest in stress as an etiologic agent for neoplastic disease (20).

EMOTIONAL STRESS AND CANCER

Is there evidence that emotional stress or psychodynamic conflict provokes or contributes to the development of neoplastic disease? A variety of hypotheses have been offered on this subject. Tarlou and Smallheiser (2) compared women with breast cancer and cancer of the cervix and concluded that women with oral conflicts developed breast cancer, whereas women with genital conflicts developed cancer of the cervix. Bacon and associates (3), after observing 40 women, felt that breast cancer could be conceptualized as passive suicide precipitated by guilt feelings and depression. Reznikoff (4) raised the question of hormonal imbalance secondary to psychodynamic conflict when he compared women with benign and malignant breast lesions and found an apparent disturbance in feminine identification and a history of excessive re-

The authors are with the Veterans Administration Hospital, Lexington, Ky. 40507, where Dr. Surawicz is Chief, Psychiatry Service, Dr. Brightwell is Chief, Behavioral Psychiatry Section, and Dr. Othmer is Assistant Chief, Psychiatry Service, and Chief, Psychobiology Section. They are also with the Department of Psychiatry, University of Kentucky College of Medicine, Lexington, Ky., where Drs. Surawicz and Othmer are Associate Professors, Dr. Brightwell is Assistant Professor, and Dr. Weitzel is Assistant Professor and Director, Inpatient Service.

sponsibilities during childhood in the group with malignant breast lesions. After psychoanalyzing 5 women with a history of breast cancer, Renneker and associates (7) suggested that there is an association between breast cancer and a disturbance of heterosexual impulses characterized by increased oral-dependent needs following disturbed object relationships. Booth (11) concluded from his work that a neoplasm involved the organ most specifically related to the frustrated psychophysiological object relationship and suggested that cancers developed as internalized substitute objects.

The concept presently known as life change units was first introduced by Greene in 1956 (5, 6). His data indicated that there was evidence of significant losses shortly before onset of leukemia and lymphoma in an overwhelming majority of the children and women that he studied. He reported that a majority of mothers of children with these disorders had been depressed and/or anxious for weeks or months prior to the onset of the child's disease. Renneker and associates (7) also reported depressive reactions prior to the onset of cancer and speculated about the possibility of decreased host resistance due to depression. More recently, Schmale (9; 10, pp 629–631) reported that cancer seems to develop in patients who report "giving up" and feeling severe hopelessness. This author suggested that giving up is a nonspecific factor that requires the existence of a neoplastic predisposition for the disease to develop. LeShan (8) summed up a consensus of many authors when he suggested that a major emotional loss precedes the development of neoplasm and raised the hypothesis that there might be a relationship between personality organization and the site of the neoplasm.

The concept of a precancerous personality or the suggestion of significant losses contributing to the development of cancer has received little attention in more recent literature, with the exception of recently published prospective studies by Thomas and associates (21–23). Her data indicated that several nonspecific personality factors correlate with the subsequent development of several illnesses.

Grissom and associates (24), in a comparative study of healthy subjects and patients with bronchial carcinoma or emphysema, found no significant difference in life change units but did report that cancer patients achieved a lower personal integration score on the Tennessee Self-Concept scales. He suggested that these individuals might have had distinct personality characteristics prior to the onset of illness. Laxenaire and associates (13) studied 80 cancer patients and concluded that there are no good data to support the theory of a specific precancerous psychological state. Finn and associates (25) found that anxiety is a common denominator of both coronary and cancer patients but that no other psychological traits distinguish these groups. Finn concluded that overriding anxiety may make it impossible to study the basic personality prior to onset of disease in these patients.

EMOTIONAL FACTORS AND THE COURSE OF NEOPLASTIC DISEASE

If it is true that stress and/or depression predispose to cancer, then there should be a relationship between degree of stress and severity of cancer. In 1954 Blumberg and associates (26) compared patients with slow-growing and rapid-growing cancers and speculated on the existence of host resistance in the first group. Such patients were variously described as manifesting normal behavior, conversion hysteria, acting out, and psychosis. Patients with rapid-growing cancers were described as characteristically suffering from anxiety and depression. Stavraky and associates (27) studied the progression of cancer and reported that patients who combined above average IQs with hostility had a more favorable prognosis. These findings conflicted with those of Laxenaire (13), who was unable to establish a relationship between the patient's level of emotional distress and the rate of progression of the cancer. More recent literature does not reflect continued interest in these speculations.

AWARENESS OF CANCER AND PSYCHIATRIC SYMPTOMS

It is possible that nineteenth-century physicians misunderstood the proper temporal relationship between melancholia and malignancy and thus saw depression as a concomitant feature of malignancy rather than as a reaction to it. Contemporary authors do not describe specific precancer histories or personality dynamics, but instead write about the reactions of patients to their illnesses. Laxenaire described intense anxiety and suicidal preoccupation (without any reported suicide attempts) as the initial response to the diagnosis of cancer (13). Bronner-Huszar (17) described anxiety as a frequent first response that in some cases led to delay in obtaining surgery because the patient denied the illness.

Anxiety is commonly followed by depression after hospitalization; one investigator found signs and symptoms of clinical depression in one-fifth of all severely ill patients studied but did not elicit suicidal tendencies or positive family histories of previous depression (28). Craig and Abeloff (29) reported high levels of depression in one-half and elevated levels of anxiety in one-third of cancer patients. Twenty-five percent of his patient group had some psychiatric signs and symptoms comparable in severity to those of patients seen in psychiatric emergency room situations. Hinton (18) reported finding the following symptoms (in descending order of occurrence) among 50 patients with diagnosed terminal illnesses: depression, anxiety, confusional states, phobic states, and manifestations of personality disorder.

To place these findings in perspective, it is important to note that one study (30) found that one-half of all patients referred for psychiatric consultation in a

general hospital suffered from depression. Feifel and associates (31) found that patients in whom death was imminent, regardless of their diagnosis, were more fearful of death than were healthy controls. Finn (25) found high anxiety profiles in both coronary and cancer patients.

Patients diagnosed as having cancer must employ coping defense mechanisms to remain in treatment and/or to achieve rehabilitation. Schonfield (14) reported a significant correlation between the ability to return to work and high scores on the MMPI well-being scale; successfully treated cancer patients also had lower scores on the morale loss scale. Bronner-Huszar discussed the phenomenon of continued invalidism in cancer patients and urged physicians dealing with them to pay attention to underlying psychological factors (17). Laxenaire placed great importance on mobilizing family support and increasing the likelihood of early return to employment as a means of effectively dealing with high levels of anxiety (13). Such an approach has led to an increased number of successfully rehabilitated patients.

Reports describing reactions of cancer patients to their diagnosis focus primarily on anxiety and depression or a combination of the two. The work of Kübler-Ross (12) explains the behavior displayed by patients who are terminally ill in terms of an adjustment to the dying experience. It is notable that this author does not regard the coping reactions of cancer patients as different in any significant way from those of other terminally ill patients. The question of whether cancer produces unique reactions deserves further investigation.

TREATMENT OF PSYCHIATRIC SYMPTOMS IN CANCER PATIENTS

A distinction between studying cancer patients and treating them must be made. Many of the papers of the 1950s evaluated patients by means of a series of tests (2–6, 26), but their treatment was not discussed. Renneker (7) suggested psychotherapy for patients in whom psychiatric evaluation disclosed a decompensating neurotic system. Treatment in these cases would be aimed at the replacement of object-fixated and frustrated drives with new sublimatory outlets. It should be remembered that psychoanalysis and psychoanalytic psychotherapy were the treatments of choice in the 1950s.

Contemporary clinicians have a much broader therapeutic arsenal at their disposal. Some questions asked by physicians who treat patients with cancer involve whether or not the patient should be helped to face the existential crisis involved in the recognition of terminal illness and death. If the physician believed that the patient should be helped to face death, pharmacological aid would be used conservatively. (The emotionally charged and controversial topic of whether to artificially prolong life does not seem to have the same relevance and intensity when discussed in terms of terminal cancer patients.)

Craig (29) strongly suggested that psychotropic drugs should be used to alleviate both anxiety and depressive symptoms. Bronner-Huszar (17) recommended judicious use of tranquilizers and antidepressants if a mental status examination indicates that psychopathology is not caused by electrolyte imbalance or drug side effects. Hinton (18) reported that he treated patients with terminal illness with psychotherapy, tranquilizers, and/or antidepressants. Kahn and Zarro (19) also suggested psychotherapy and selective use of medications for the management of terminally ill cancer patients, and Laxenaire (13) emphasized the involvement of the physician as well as the family in the management of these patients. Such involvement is not without its price, since the management of terminal patients places heavy demands on the physician (32). LSD has been prescribed for use with terminal patients (33). Recent literature has emphasized the physician's obligation to try to give support and comfort to patients suffering from any terminal illness, including neoplastic disease.

DISCUSSION

Early studies tended to search for specific personality types, defined in terms of psychodynamic variables, associated with specific cancer types. Difficulties with this approach resulted from the lack of carefully designed longitudinal studies (34). In addition, most studies did not have control groups; the few that did used poorly matched controls. In many cases the authors failed to consider the impact that having cancer might have on an individual's answers in an interview or on psychological tests. In the absence of control groups, one cannot assume that these answers were the same as those the patient would have given prior to the diagnosis of cancer. As more carefully designed studies have been carried out, the concept of a specific carcinogenic personality has not been supported.

While the search for a specific personality associated with cancer so far has come to a dead end, there does appear to be some association between the course of illness and several nonspecific personality factors. Perhaps individuals with certain personality traits adapt poorly both psychologically and physiologically to any of several diseases and syndromes (35). Recent investigations have been concerned with emotional and behavioral reactions after the diagnosis of cancer has been made. It seems clear that depressive symptomatology is common, but the treatment of choice, if any is even indicated, has not been established.

There continues to be much interest in the relationship of emotional symptoms, psychiatric disease, and the onset and course of neoplastic disease. Final understanding continues to elude us. We do well to remind

ourselves that all illnesses have both physiological and psychological components. If one acknowledges the unity of body and mind and remembers that man is a member of a family and society, one easily recognizes the wide repercussions that terminal illness has. Such an awareness requires the physician not only to treat the cancer process per se, but also to mobilize and involve the patient and his family in the successful confrontation with this final life crisis.

Trends in Hospital Versus Community Treatment of Mental Illness: A Texas Example

BY JAMES L. CLAGHORN, M.D., GEORGE W. MCBEE, PH.D., AND LINDA ROBERTS, M.A.

The authors present statistics from Harris County, Tex., that indicate community psychiatry is making progress toward its goals of decreasing inpatient hospitalization and increasing services to the community. At the present ratio of services, a 30%–40% increase in outpatient services could theoretically eliminate the inpatient system. The authors stress the fact that inpatient facilities are still vital and offer directives for the future roles of the hospital and of community psychiatry.

SINCE THE INCEPTION of the community mental health movement in the early 1960s, mental health professionals have continued to search for methods to provide optimum patient care. While all agree that long-term hospitalization, custodial care, and huge institutions belong to a dark antiquity, heated polemics erupt among professionals concerning the issue of the psychiatric hospital. Those who support the community movement point to the dehumanization and ineffectiveness of traditional hospital treatment and demand the abolition of such institutions. Equally adamant are those advocates of the "patient's right to be a patient" who defend the hospital and the medical model in psychiatry (1). Others take the middle-of-the-road position that we should integrate community and hospital programs to develop a unified human services system (2–4).

In keeping with the promises of the community movement, mental institutions have experienced reductions in both capacity and admissions. Unfortunately, a scarcity of data exists on the relationship between these reductions and the use of community programs. A study conducted at the Prairie View Mental Health Center in Kansas (5) showed a significant decline in state hospital admissions attributable to services delivered by a comprehensive community system. However, an investigation in San Antonio, Tex., revealed an increase in the number of admissions to the state institution in a catchment area in which community services were available (6). The latter results must be viewed from a different perspective since the community and hospital services were integrated in a comprehensive program and the community center served a patient population that far exceeded the capacity of the hospital alone.

Another concern that has evolved during this era of community psychiatry is whether the system can adequately reach and treat the population in need of services. Two studies done in the early years of community psychiatry attempted to assess the mental health of general populations. The Midtown Manhattan study (7) examined the nature and prevalence of symptoms of mental illness in relation to socioeconomic status in an urban area, and the Stirling County study (8) investigated symptoms of mental illness in relation to the individual's integration into a rural community; data from both projects revealed that approximately one-third of their populations exhibited major symptoms. Community service systems have not yet reached their projected capacities. But in the face of this great potential need, efforts seem futile and present systems seem hopelessly inadequate; the professional is besieged by doubts that present and planned mental health facilities can provide the care necessary.

At its inception the community mental health model was looked upon as a modern, humanistic approach to treatment that would eventually close traditional institutions and provide comprehensive services to the entire population in need. At present some of the problems in achieving optimum patient care center about these issues—i.e., the ability of community programs to deliver adequate services, the future of the psychiatric hospital, and the relationship between reductions in state hospital admissions and the use of community facilities. An examination of recent trends in public hospital and outpatient treatment based on statistics from Harris County, Texas, elucidates some aspects of these problems and suggests directions for the future.

TREATMENT TRENDS IN HARRIS COUNTY

Population growth in Harris County has been great and is expected to continue at the present rate. The treatment trends that we will discuss have been occurring during this growth phase; therefore, little change is expected in them in the coming four or five years. Of course, the rate of population growth is subject to economic and social influences and may unexpectedly in-

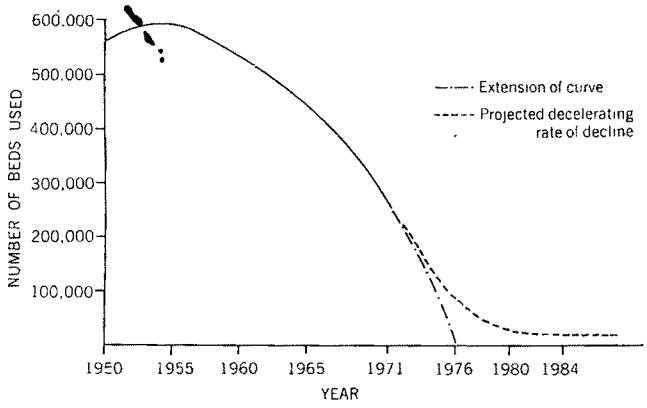
FIGURE 1
Number of Public Inpatient Psychiatric Beds Used Nationally from 1955 to 1971, and Possible Future Trends



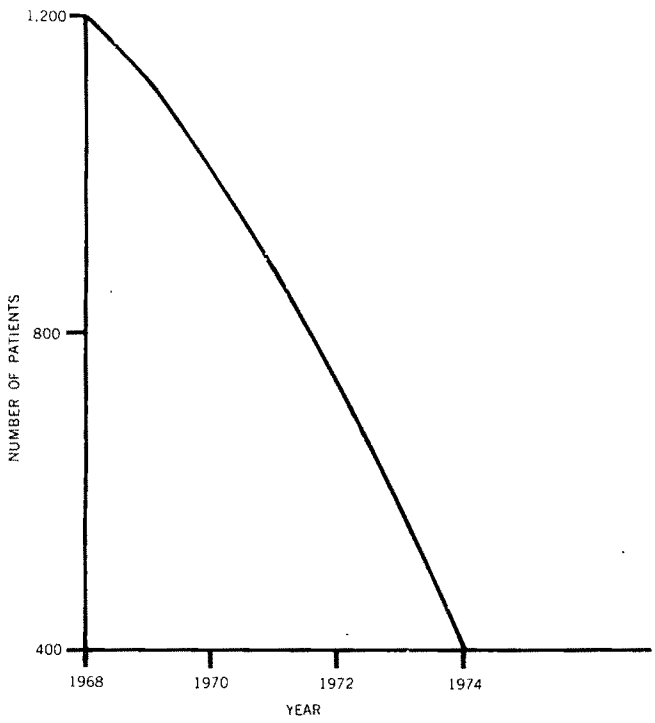


FIGURE 2
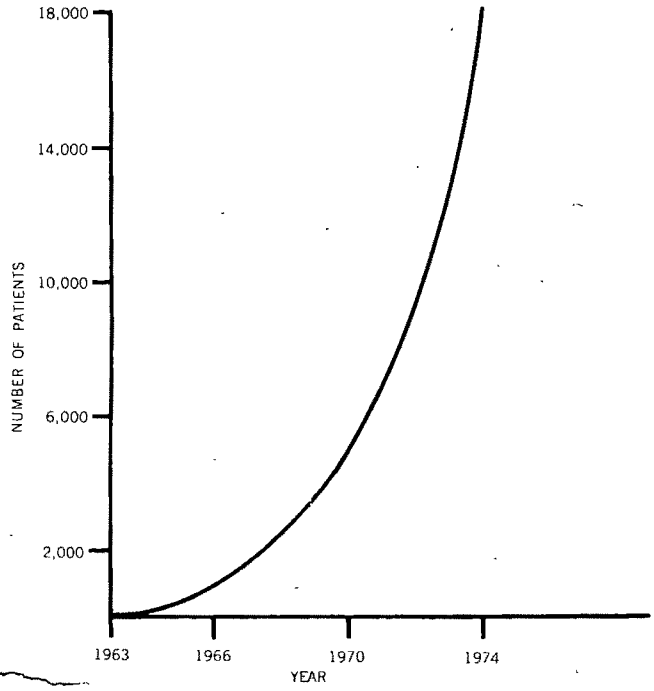
Number of Public Psychiatric Inpatients in Harris County from 1968 to 1974

crease or decrease, but an analysis of recent trends can still be instructive and beneficial in planning.

Since 1955, the number of public beds used by psychiatric inpatients nationally has been declining at a rate that has increased from 3% in the first years to 10% in 1971 (9). Figure 1 shows the rate of this decline. If the curve is extended without inflection it reaches a baseline of 0 in 1976; if we assume a decelerating rate of decline, the result is a reduction in bed need to some irreducible minimum.



A 10% annual rate of decline was also noted for Texas in a report made in 1974 (10); this rate also applies to the Harris County unit of the Austin State Hospital. Figure 2 illustrates this decline in the number of Harris County inpatients from 1968 to 1974. In 1968, when the geographic units of the Austin State Hospital were formed, the Harris County unit had a capacity of approximately 1,100 patients. The Jefferson Davis Hospital and the Texas Research Institute of Mental Sciences in Houston jointly provided a few more than 100 additional beds, a number that has remained relatively constant since that time. By contrast, the number of inpatients in the Harris County unit of the Austin State Hospital has declined to approximately 300. Thus the average number of hospitalized psychiatric patients from Harris County recently totaled about 400—an admissions rate that is slowly and continuously declining.

Community services began at the Texas Research Institute of Mental Sciences in 1963 with 300 outpatients referred from the Austin State Hospital. This clinic has grown steadily and has been joined in its effort by the Mental Health and Mental Retardation Authority of Harris County. In 1974 this community program had a total outpatient capacity of approximately 18,000 patients; figure 3 illustrates an approximate growth rate for outpatient treatment. This rate must be considered approximate for several reasons: reluctance by the clinics to inactivate files of patients who missed appointments or lost contact with them, difficulties in using comparable measures (e.g., whether only those patients who are active at the close of the year, or all patients who have been active during the year, are counted), and a lack of communication among the clinics which may cause one person to be considered active by more than one clinic. These problems usually lead to an overestimation of clinic population.

Allowing for some overestimation of the size of the population treated, it can be seen by comparing figures 1 and 2 with figure 3 that the growth rate for outpatient treatment is nearly reciprocal to the decreased rate of inpatient care. The rate of outpatient growth is about 20 times that of inpatient reduction; that is, 15–20 outpatient service units will absorb 1 hospital service unit. If this ratio is applied to the recent total Harris County census of 400 beds, an interesting projection can be made: 6,000 to 8,000 additional outpatient service units—an increase of 30%–40% over current levels of service—might eliminate the entire inpatient system.

While this projection is entirely theoretical, it indicates that community mental health programs in Harris County are progressing favorably and that community psychiatry is fulfilling one of its purposes in assuming the care of patients who previously required hospitalization. Furthermore, outpatient facilities are delivering services to many more clients than was possible before community programs were instituted. In 1968 hospital capacity was at a maximum of 1,200 patients; outpatient services are currently received by 18,000 clients. These numbers demonstrate the sys-

FIGURE 3
Number of Public Psychiatric Outpatients in Harris County from 1963 to 1974

tem's potential to reach and treat the population in need.

NEED FOR A COMPREHENSIVE SYSTEM

General directives for the future of community mental health can be drawn from the representative trends shown here. The surprising projection that all hospital beds could be eliminated by a moderate escalation of outpatient services underscores the need for continued growth of community facilities. Steady increases in outpatient services would raise the size of the population treated; if carried out modestly and at regular intervals, these increases would comply with budgetary restrictions. It is vitally important to maintain adequate levels of outpatient service since long waiting lists and undue delays would undoubtedly drive many patients back to the hospital.

Community services and hospital care should be well integrated in a comprehensive system. The psychiatric hospital is still vital to this system; intensive chemotherapy with severely disturbed patients is best administered in a medically supervised setting. The milieu and style of the hospital is changing and should continue to change. Long-term custodial treatment has given way to acute short-term treatment and prompt discharge. Ideally, this treatment should occur in small, community-based inpatient facilities.

Community mental health has effected many changes in psychiatric treatment. The system has already progressed significantly toward its goals but requires continued, conscientious planning to achieve its potential. For this reason research is crucial to the future of community psychiatry. However, a paucity of supportive data exists in this area. A concerted effort must be made to evaluate programs and to assess their therapeutic outcomes; this base of data is essential to the structuring of comprehensive community service systems.

Who Gets Supervised? An Extension of Patient Selection Inequity

BY RODNEY W. BURGOYNE, M.D., SANDRA SANTINI, M.S.W., FRANK KLINE, M.D., AND FRED R. STAPLES, PH.D.

A study of 89 individual psychotherapy patients followed by 17 residents in a teaching clinic demonstrated that those presented for supervision significantly differed from the others in being younger, better educated, and better liked by residents and in having higher incomes and longer term treatment. The authors discuss the implications of these findings in relation to the inequity in service time and teaching emphasis that this selection allows.

THERE IS CONSIDERABLE evidence that psychotherapists prefer patients of the opposite sex who are young, attractive, verbal, intelligent, and successful (the YAVIS syndrome of Schofield) (1–3). Such patients are more likely to be offered longer treatment and to remain in it (4–7).

Like many other facilities, the Adult Psychiatric Outpatient Clinic of the Los Angeles County–University of Southern California Medical Center primarily serves middle- and lower-class patients. While psychiatric supervisors and residents apparently endorse the policy of providing relevant psychotherapy for the poor and unattractive, actual service lags behind the ideal. Resident psychotherapists arrange their own individual work load, may choose to see patients or not, and may choose the treatment modality. About one-half of all patients in individual psychodynamically oriented psychotherapy are regularly presented to a senior staff member for supervision. Thus residents make decisions about patients in individual psychotherapy at the following 3 stages of the treatment process: initial acceptance or rejection, whether or not to present the patient for supervision, and the type of disposition arranged for the patient when the resident leaves the clinic service.

The purpose of this study was to determine whether selection procedures similar to those operating at the initial selection/rejection decision also operate when trainees present long-term patients to supervisors and subsequently arrange further treatment for them.

The authors are with the University of Southern California, Los Angeles, where Dr. Burgoyne is Assistant Professor of Psychiatry, Dr. Kline is Associate Professor of Psychiatry, Dr. Staples is Associate Professor of Psychiatry (Psychology), School of Medicine, and Ms. Santini is Preceptor of graduate students, School of Social Work. Drs. Burgoyne and Kline are also Associate Directors and Ms. Santini is Psychiatric Social Worker, Adult Psychiatric Outpatient Clinic, Los Angeles County–University of Southern California Medical Center, 1237 North Mission Rd., Los Angeles, Calif. 90033.

METHOD

Seventeen second-year residents completed a questionnaire on patients they had in treatment, indicating the type and duration of psychotherapy. Because the residents were to leave the clinic soon, they listed their plans for each patient's disposition. Residents could continue individual therapy with up to 3 patients, but the others were to be discharged, transferred, or referred.

All residents were then interviewed to determine the frequency of regular supervision for all individual therapy patients seen at least weekly for over 2 months. Additional information was obtained from a second semistructured interview regarding patients treated 9 months or more, and other information was gathered from charts and intake forms.

RESULTS

Residents provided longer treatment to patients whose psychotherapy was regularly supervised. Residents received supervision for 42% of 109 patients seen for 2 to 8 months, compared with 66% of 89 long-term patients treated for over 8 months. Table 1 compares data on the 59 supervised and 30 unsupervised long-term patients.

In spite of jokes to the contrary, female patients were no more likely to be presented to supervisors than male patients. In both groups twice as many women were seen as men, but with an equal proportion presented for supervision. Male patients treated by 3 female residents were always supervised, although their patient load was 85% female.

Differences in age, education, and income were related to supervision. Chi-square analysis revealed that significantly fewer of the older, less educated, and poorer patients received supervised treatment. Older female patients rarely had supervised treatment, and no one of either sex who had less than a high school education received any regularly supervised therapy. Patients diagnosed as psychotic were less likely, and those with personality and/or character disorders were more likely, to receive supervised psychotherapy.

*Schizophrenia and psychotic depression.

Whether or not residents found patients "personally appealing" people and whether or not they believed their patients "benefited" from psychotherapy were not correlated with supervision. However, a strong trend indicated that "liked" patients were more frequently supervised, and ongoing regular supervision was significantly related to residents' "feeling involved" with their patients.

Differences in plans for patient disposition were highly correlated to supervision. Residents planned to continue individual psychotherapy with half of the patients whose treatment was supervised, but with only 1 in 10 of the unsupervised group. Residents more often planned group therapy, referral, and discharge for the latter group and were more frequently uncertain about their disposition. Actual disposition was

very similar to planned disposition. Indeed, supervision did not significantly influence adherence to disposition plans. Except for those patients for whom plans were uncertain, actual disposition was almost always as planned.

DISCUSSION

Young, attractive patients who appear to have good ego strength, high education, and a good income are most likely to be selected for supervision. Other studies have indicated that residents treat patients who are similar to themselves (8, 9). Our survey demonstrates that this is even more true of patients presented for supervision. The generation gap influences which patients residents select for supervised treatment. They avoid men and almost totally exclude women over age 35. Thus the psychiatric problems of older groups are avoided at a crucial point in residency training. As the population moves toward older ages, skills to manage the problems of older patients are critically needed.

Supervision influences plans for patient disposition principally by encouraging residents to either continue more patients in individual therapy or discharge them rather than referring them elsewhere. This suggests that supervisors influence residents to believe that their supervised patients are special and should be continued in individual therapy or that they have finished their treatment.

Patients initially selected for individual psychotherapy are not representative of the general clinic population. Those selected for supervision are even less representative. Residents spend the majority of their time and most of their supervision on patients who least need treatment. They are best trained to treat the healthiest people, with less emphasis on skills required to treat the majority of patients. This type of selection may be one reason why so many practicing psychiatrists are reluctant to treat the sick and the poor, which in turn may be one of the reasons why federal and local funding agencies have become discouraged in their efforts to train and increase the number of psychiatrists.

Supervisors should make a conscious effort to encourage residents' interest in the so-called "less desirable" patients. This requires readjustment of some of their own goals and interests. It is not surprising that supervisors who have been primarily trained in dynamic psychiatry overvalue individual, long-term, dynamic psychotherapy (10). That is what they know and practice, and that is what they therefore prefer to teach. It is understandable, but unfair, when this attitudinal priority distills onto trainees.

It has been our experience that supervisors, when asked, can and do make necessary adjustments in their own value systems, call upon their long experience augmented with any necessary new information, and become more relevant and helpful in their supervision and teaching. This process requires continuing reinforcement from administrators, particularly when teaching supervisors are private practitioners who themselves treat patients from middle and upper classes. The effort required of all is amply rewarded by the increased relevance of supervision to the patient population.

Studies of Adoptees from Psychiatrically Disturbed Biological Parents: III. Medical Symptoms and Illnesses in Childhood and Adolescence

BY REMI J. CADORET, M.D., LYNN CUNNINGHAM, M.D., ROSEMARY LOFTUS, M.S.W., AND JAMES EDWARDS, M.D.

Analysis of data gathered from interviews with adoptive parents supports the hypothesis that female adoptees of antisocial biological backgrounds might have higher percentages of somatic symptoms. The authors compared female adoptees of antisocial parentage with male and female controls, male adoptees of antisocial parentage, and male and female adoptees whose biological parents had other psychiatric conditions. They stress the importance of this hypothesis in the diagnosis and management of childhood and adolescent "medical" and behavioral problems.

IN PREVIOUS REPORTS (1, 2) we have presented behavioral findings from two groups of adoptees with different biological backgrounds. In one group (N=59) biological parents suffered from a variety of psychiatric conditions (experimental adoptees); in the second group (N=55) there was no recorded pathology in either biological parent, and adoptees were matched for relevant factors such as age and sex.

The main behavioral findings contrasting the two adoptee groups were increased incidence in experimental adoptees of 1) childhood hyperactivity in males, 2) behavior disorder requiring professional treatment, 3) antisocial behaviors and temperament traits characteristic of the "difficult" child in males, and 4) hyperactivity (mainly in males) in those who had an antisocial biological parent compared with those whose parents had other psychiatric diagnoses.

One of the primary findings, the overrepresentation of males with psychopathology, raised the question of whether female children or adolescents might manifest psychopathology differently than males. Such a possibility is suggested by studies that have related hysteria in females (characterized chiefly by multiple somatic complaints without a medical basis) to parental antisocial personality or hysteria (3). In hysteria, the somatic symptoms usually commence in childhood and adolescence. Furthermore, studies of adult antisocial individuals indicate that a high percentage have multiple somatic symptoms, such as anxiety attacks, dizzy spells, weakness, etc. (4). Rutter (5), in his population survey of children on the Isle of Wight, reported that psychiatrically disturbed girls had high incidences of stomachaches, eating difficulties, aches and pains, and absences from school for trivial reasons compared with psychiatrically disturbed boys, who did not show higher percentages of these behaviors than were found in the general population. These data suggest that one of the manifestations of a childhood psychiatric disturbance, especially personality disorder, can be multiple somatic symptoms and that females might be more likely than males to manifest these kinds of symptoms.

This paper supports the hypothesis that female adoptees of antisocial biological backgrounds might have higher percentages of somatic symptoms. We shall also report on related medical aspects of childhood illness and medical utilization, such as hospitalization and physician visits.

METHOD

Our previous reports (1, 2) detailed the selection of adoptees and the conduct of the structured interview with the adoptive parents to determine childhood and adolescent behaviors. At the time of the parental interview the median age of the adoptees was 17. Interviews were conducted by a professional social worker who was blind to the adoptee's group (control or experimental).

A number of questions covering physical health during infancy, childhood, and adolescence were asked. Our analysis organized these questions into the following areas:

1. Multiple somatic complaints, determined by the number of affirmative answers to whether the adoptee missed school a lot because of sickness, complained a lot of aches and pains without cause, was sickly as a child, fainted, had nervous problems with somatic symptoms (e.g., nervous stomach, headache), had

Dr. Cadoret is Professor, Department of Psychiatry, University of Iowa College of Medicine, Iowa City, Iowa 52242. Dr. Cunningham is in private practice in Springfield, Ill. Ms. Loftus is Social Worker, Barnes and Renard Hospital, and Dr. Edwards is Clinical Associate Professor of Child Psychiatry, Washington University, St. Louis, Mo.

unexplained medical problems, and/or experienced menstrual problems (e.g., irregularity, cramps).[1]

2. *Medical utilization*, defined as the number of visits to the doctor per year and the number of hospitalizations in a lifetime.

3. *Childhood physical illness*, i.e., whether the adoptee had had one or more usual childhood illness (measles, mumps, chickenpox, etc.) and other acute or chronic illnesses or operations.

Frequency distribution of scores of each of these three areas were made separately for males and females, comparing controls and experimentals and contrasting within the experimental group adoptees of antisocial biological parentage with those whose biological parents had other psychiatric conditions. Differences between distributions were analyzed by the Mann-Whitney U test (8). Two-tailed probabilities are used throughout in reporting significance levels.

RESULTS

The main findings in our study concerned somatic complaints. In general, the female adoptees registered more somatic complaints than the males even when menstrual problems were excluded, although the difference in numbers of somatic symptoms (excluding menstrual ones) was significant only at the 10% level (two-tailed, $p=.068$, U test). This difference makes comparison within sexes mandatory. Experimental female adoptees from antisocial parentage had significantly more somatic complaints than both the female controls ($p=.016$) and the remainder of the experimental females ($p=.008$). The corresponding differences for males are similar but not significant by themselves.

Both the frequency distribution of yearly visits to doctors and the frequency distribution for lifetime hospitalization showed no differences when we compared experimental with control probands or probands of antisocial background with remaining proband groups.

Almost all adoptees had had the usual childhood illnesses such as chickenpox or mumps. Other major medical illnesses that occurred in the adoptees were asthma, hepatitis, meningitis, pneumonia, scarlet fever, etc. There are no overall differences between the groups in number of major illnesses. There appears to be a nonsignificant trend for more severe illness to be reported among female adoptees from antisocial backgrounds (5 out of 10 had severe illness) as opposed to that reported in the remaining experimental female adoptees (2 out of 17 had severe illness).

Because this trend for more severe illness might be associated with such consequences as missing school, fainting or similar symptoms, or labeling a child as "sickly," we reanalyzed our original data on multiple somatic complaints, including only items that were not likely consequences of having a more severe physical illness (complaints of aches and pains without cause, nervous problems with somatic symptoms, unexplained medical problems, and menstrual problems). The results were similar, i.e., the female adoptees from antisocial biological backgrounds had more somatic complaints when compared with the control group ($p=.03$) or with the remaining experimental adoptees ($p=.05$).

[1]Some of these items are often reported positive in studies of hysterics (6, 7), and several cover functional symptoms characteristic of neurotic or hysteric individuals (e.g., fainting, nervous stomach).

DISCUSSION

We found more complaints of medical symptoms in female adoptees from antisocial biological backgrounds. The quality of the complaints appears to relate more to behavioral problems (reporting aches and pains without cause) or functional problems (nervous stomach, headaches, menstrual cramping and irregularities) and is similar to the types of symptoms reported in hysterics (6), although none of the female adoptees in this study had enough symptoms to qualify for a diagnosis of hysteria. This finding of more somatic complaints among daughters is consistent with the family studies that reported increased incidence of hysteria among the daughters of antisocial women (3). Unfortunately we do not know the long-term outcome of these adoptees, i.e., how many would eventually qualify for a diagnosis of hysteria or Briquet's syndrome.

In another adoptee study of offspring of antisocial women, Crowe failed to find hysterics among the daughters (9); he also found that somatic complaints in these daughters of antisocials were no more frequent than in a matched control group of female adoptees (10). However, certain differences between the two studies could account for the lack of somatic complaints in the Crowe data. His study, in which each interviewed adoptee received a medical review of systems aimed at symptoms occurring mainly during adulthood, did not specifically examine childhood or adolescent behavior; he also did not interview parents about malingering or exaggeration of symptoms in their children. Our study examined both of these areas.

CONCLUSIONS

The only significant difference between females in this study was the finding of increased somatic complaints in experimental female adoptees of antisocial backgrounds. The nature of their complaints was similar to that reported by Rutter (5) in his study of psychiatrically disturbed female children in the Isle of Wight. Our male adoptees, by contrast, showed a number of significant differences, with the experimental adoptees having a higher incidence of behavioral conditions requiring professional care, childhood hyperactivity, antisocial behavior traits, and temperament traits characteristic of difficult children (2). Whether

these are sex-influenced genetic differences is a question for further research. The possibility that psychiatric disturbance could manifest as multiple somatic symptoms in females is important clinically in the diagnosis and management of childhood and adolescent "medical" and behavioral problems.

Male Transsexuals in the Homosexual Subculture

BY EDWARD M. LEVINE, PH.D.

The author describes 20 male transsexuals who differ from most discussed in professional studies and from those in media portrayals in that they live in the male homosexual subculture. Furthermore, interviews with these individuals indicated that transsexuals are no more sexually or socially homogeneous than heterosexuals or homosexuals. In general, these men entered the homosexual subculture in their teens; they knew they were not heterosexual and therefore assumed they must be homosexual. As their gender identity crystallized, homosexual activity became repugnant and they rejected and were rejected by male homosexuals. Being unable to attract heterosexual men, they sought bisexual partners in a futile effort to confirm their identity as females. The author suggests that in addition to efforts to help transsexuals shift their gender identity, psychiatrists should emphasize prevention of this psychopathologic symptom.

THE PHENOMENON of transsexualism has recently caught the public's attention. It has been incorporated in college courses on various aspects of human sexual behavior and has been the subject of a number of television panel and interview shows over the past few years. However, most of what is discussed or portrayed about transsexualism is restricted in content and perspective, largely because of the nature of the group of transsexuals about whom most is known.

The great majority of men whose transsexual identity has been confirmed by psychiatric diagnosis have been unknown as such to anyone but the diagnosticians and others whose assistance they have sought. These individuals seem to lead ordinary lives—they are employed in a variety of occupations where their attire and sex roles and general social behavior are male. In addition, their lives seem to differ little, if at all, from those of others in the heterosexual communities in which they live. Indeed, when they decide to become full-time, cross-dressing transsexuals, their social acquaintances are shocked because they have had no inkling that this metamorphosis was being considered or was even possible. Such male transsexuals characteristically avoid contact with other sexual deviants, including other male transsexuals and homosexuals, and are not involved in prostitution. Thus they might fairly be depicted as "straight" middle-class people, a description that is either implied or stated in the literature.

There are, however, other psychiatrically confirmed

Dr. Levine is Professor, Department of Sociology, Loyola University, Chicago, Ill. 60626.

male transsexuals whose life-styles contrast markedly with the majority of those about whom we have information. The discussion that follows, which is an extension of previous research (1, 2), is based on interviews with 20 transsexuals[1] who live in the male homosexual subculture; the transsexuals' homosexual acquaintances were also interviewed. These interviews indicated that there are increasing numbers of male transsexuals who live in this subculture and whose problems and life-styles are much like those of the men in this sample, who stated that they knew many others like themselves.

The information gained about certain key aspects of the lives of the individuals in this sample provides an added dimension to our knowledge about transsexualism, if only because it indicates that transsexuals are no more socially or sexually homogeneous a group than are other sexual deviants or heterosexuals.

Much of the literature on male transsexuals has focused on their more obvious problems and tensions and has emphasized ways in which they can and should be assisted. One of these methods is sex-change surgery, which is intended to provide a more effective adjustment to the transsexual gender and psychosocial identity. Sensitivity to and familiarity with the transsexuals' plight are translated, quite understandably, into a genuine professional desire to alleviate their problems when at all feasible.

This outlook has been supplemented in recent years by the appearance on television shows of male transsexuals who have changed gender. Characteristically, these programs do not raise questions about the etiology of transsexualism, much less discuss the question of whether or not it is a psychopathologic symptom. This is due, in part, to the assumption that viewers would be bored by time-consuming technical explanations. Inasmuch as those in charge of television programming are always looking for novel subjects to maintain and boost their audience ratings, it is finances, rather than social responsibility or mental health considerations, that dictate how topics on sexual deviance will be presented to an impressionable audience.

Understanding of and sympathy toward transsexualism on the part of the public and of professionals are increasing. One impression that is easily drawn from media presentations is that there is an "average" male transsexual. However, there are transsexual men who are six feet tall and taller, weigh 200 pounds and more, and have body configurations that stamp them unmistakably as men no matter how successful they are in modifying their bodies, apparel, mannerisms, and tone of voice. Will such tragic figures really convince anyone, particularly the heterosexual men they so desperately wish to attract, that they are females?

Of course it is important to attempt to assist transsexuals in solving their problems; it is, however, equally important to recognize that transsexualism is a psychopathologic symptom and that appropriate attention and concern should be given to its prevention (3). It is from this perspective that I will examine certain aspects of the interpersonal relationships of male transsexuals in the homosexual subculture that add psychological problems to their already burdened lives.

TRANSSEXUALS: THE HOMOSEXUAL PHASE

The transsexuals in this sample went through two transitional phases. The first was during their late teens when they were introduced to the male homosexual subculture by homosexuals who befriended them at a time when they assumed that they "must" be homosexual, since they knew they were not heterosexual. A factor that "confirmed" this belief was that all of them had been involved in homosexual relations, although they were invariably passive and never actively pursued a homosexual partner. The second phase involved their complete detachment from homosexuals, their new relationships, and the problems this change entailed.

Entering the male homosexual subculture provided these men with an enormous sense of relief from the tensions they had suffered from having to hide their "homosexuality" from parents and friends.[2] Upon severing their relations with their families, they moved permanently into areas near bars that cater almost exclusively to male sexual deviants. However, as their sense of gender identity began to crystallize, they gradually realized that they were *not* homosexuals, and homosexual activity had become repulsive to them. Consequently, their once close personal relationships with male homosexuals grew cool and distant. As they withdrew from these relationships, the homosexuals they had been close to began to view them as "women" and, therefore, as sexually repugnant.

Furthermore, the transsexuals had become competitors with the homosexuals for male bisexual partners for sex and, to a lesser extent, for companionship. The homosexuals became openly depreciating of and insulting toward the transsexuals and vilified them in their comments during interviews. (Competition among male heterosexuals for partners is less intense because they are less driven by sexual and personality compulsions, and because their lives are more generally governed by social norms that effectively mitigate any hostilities they may have toward perceived competitors.)

[1]I should note that there is no way in which the sociologist can determine the accuracy of the psychiatric diagnoses that confirmed these individuals' claims of transsexuality. However, two individuals were subsequently approved for sex-change surgery, so there seems to be some basis for their claims and the correctness of the diagnoses.

[2]Field research indicated that female-to-male transsexuals almost invariably patronize lesbian bars, thereby maintaining a pattern of sex-role segregation that sharply contrasts with many contemporary heterosexual sex-role trends.

Transsexuals are often receiving estrogen and are therefore less driven by sexual impulses. However, their consuming need to prove that they are women leads them to search constantly for a heterosexual male who, in their minds, is the only person who can confirm their identity as women. However, they can not attract such individuals and are, therefore, obliged to turn to bisexual men.

The transsexuals in this sample had been or, when interviewed, were involved in prostitution—unlike, it should be recalled, most of the transsexuals who have been described in the literature. All of them said they did this in order to supplement their incomes, since they had, for a variety of reasons, quit their jobs (or in the case of a few of the youngest, had never been gainfully employed) and were dependent on welfare. None of them was happy about having resorted to prostitution, and their major source of satisfaction (aside from the income) was deceiving heterosexual males into assuming they were consorting with females.

RELATIONSHIPS WITH BISEXUALS

Sooner or later, these transsexuals found a male bisexual lover to decrease their intense loneliness and in an ill-disguised and futile effort to prove that they could attract and keep the attentions of a "heterosexual" male. However, it was common knowledge that their lovers were bisexual. What was less generally known, however, was that some of these bisexuals frequently prevailed on their transsexual "mistresses" to resort to prostitution to supplement their incomes, for most of the bisexuals were not employed full time or held low-paying jobs.

That the transsexuals yielded to this manipulation was evidence of their extreme dependency on the bisexuals for companionship and sex, which was heightened by the fact that the bisexuals were invariably dominant in these relationships. In addition, the bisexual partner alone could maintain the facade of female heterosexuality that the transsexuals so desperately wanted.

As might be suspected, the living arrangements of the transsexuals and their bisexual lovers were set up chiefly to suit the convenience and whims of the bisexuals who offered no assistance in taking care of household tasks, and generally felt free to come and go and spend money as they wished. These situations were not merely a contemporary reflection of more traditional living arrangements of heterosexual couples; they clearly expressed the unquestioned dominance of the bisexuals, whose domineering personalities, not simply the preferences and needs of lovers, took priority over all other considerations. It is no exaggeration to say that these bisexuals were examples of male chauvinism at its worst.

The lives of the transsexual men in this sample were riddled with unpleasant experiences in their relationships with homosexual acquaintances and with bisexual lovers. They were depreciated and degraded by other sexual deviants, which they had not anticipated and which counteracted the personal gains they felt they had achieved in being able to live openly as transsexuals. Informal comments during one of the interview sessions indicated that professional and public acceptance of male transsexuals will not cause their personal problems to vanish. These problems stem from their male anatomies and sense of female gender and from their clearly weak, dependent personalities (3, 4).

INTERPERSONAL PROBLEMS AMONG MALE TRANSSEXUALS

The personality disturbances of these men had a considerable effect on their social relationships with other transsexuals. It was assumed that individuals whose lives are so beset with difficulties would be particularly sensitive and sympathetic toward others like themselves. Surprisingly, the opposite proved to be the case. They did not seek each other out as roommates in order to share expenses and gain companionship and commiseration; in fact, they very rarely invited other transsexuals to their apartments. Aside from meeting other transsexuals in homosexual bars, their social life was meager.

The underlying reason for this seemed to be their deep-seated emotional insecurity, which was expressed in their deprecatory comments about other transsexuals. Those interviewed were asked to estimate the number of transsexuals in Chicago (estimates ranged from 75 to 500) and then were asked how many they knew personally. At this point, they said they really doubted that the others they knew were truly transsexuals. They criticized them for their lack of femininity, which they believed manifestly established transsexuality, or expressed their underlying resentment by casually suggesting that they were attempting to "pass" as transsexuals but were actually "drag queens." Inasmuch as they could not have known (except in cases of close personal acquaintances) whether these individuals had been psychiatrically confirmed as transsexuals, it was clear that they were attempting to shore up their emotional insecurities by denying or raising serious doubts about the transsexualism of others.

COMMENT

There is reason to suggest that increased social acceptability of various forms of sexual deviance will result in more transsexuals recognizing their transsexuality earlier, seeking to openly establish it sooner, and more casually adopting the life-style appropriate to their transformation in gender identity.

Given this possibility, it is appropriate to ask if it is not now time to shift the emphasis from a responsible

professional desire to help transsexuals to one which, while not abandoning this perspective, directs attention to the psychopathologic character of transsexualism and encourages improved parenting in order to avoid the development of transsexualism. What I am suggesting is that as much emphasis be placed on prevention as on procedures designed to facilitate social and anatomical changes in transsexuals' transitions from male to female. Obviously, this responsibility can be most effectively assumed by psychiatrists.

Problems in the Differential Diagnosis of Narcolepsy Versus Schizophrenia

BY BRUCE SHAPIRO, M.D., AND HENRY SPITZ, M.D.

The authors discuss the problems of accurately diagnosing narcolepsy when patients manifest the auxiliary symptoms of this disorder, i.e., cataplexy, hypnagogic hallucinations, and sleep paralysis, which often seem to indicate a psychiatric diagnosis. They conclude that misdiagnosis of narcolepsy can be avoided if clinicians are aware that this illness can simulate a psychiatric disorder and if they give careful attention to the history of the patient's illness.

OVER THE PAST 20 years the recognition and understanding of sleep disorders have received increased attention in the psychiatric literature. The major impetus for this development was the electroencephalographic elucidation of man's sleeping state. Aserinsky (1), Kleitman (2), Dement (3), and others revealed that sleep normally proceeds in various stages, and that the difference between wakefulness and sleep is not akin simply to the difference between day and night.

It is now known that EEG tracings of "normal" human sleep are characterized by four nonrapid eye movement (NREM) and one rapid eye movement (REM) stages. With the aid of electroencephalography, electrooculography, and electromyography, it has been established (4) that the healthy adult shifts from wakefulness to stage I sleep, characterized by an EEG pattern of relatively low voltage and mixed frequency. Stage I sleep is followed by stage II (characterized by 12-14 Hz sleep spindles), which in turn makes a transition to stages III and IV (both characterized by slow waves of 1-2 Hz, with stage III showing fewer slow waves than stage IV). Approximately every 70 to 90 minutes this series of sleep events is interrupted by rapid eye movements and generalized hypotonia (except for the extraocular and respiratory muscles), along with numerous other physiological changes and an EEG pattern similar to that of stage I sleep. This is the commonly referred to REM stage of sleep, which occurs with some regularity among the NREM stages with increasing frequency during the night.

Thus the healthy adult is engaged in a rather complicated series of central nervous system changes during the still mysterious one-third of life that we call sleep. In some persons the length, order, regularity, or relationship to wakefulness of these various stages deviates significantly from the statistical norm. One resulting sleep disorder is narcolepsy.

NARCOLEPSY AND ITS AUXILIARY SYMPTOMS

Narcolepsy ("sleep attacks") is a disorder of the sleep-wake cycle characterized clinically by the sudden, often irresistible urge to sleep. Gelineau (5) first named the disorder in 1880, and a classic description was written by Daniels in 1934 (6). Recently several excellent clinical descriptions and literature reviews have appeared (7–9). The work of Hishakawa and asso-

The authors are both with New York Medical College, New York, N.Y., where Dr. Shapiro is Instructor of Psychiatry and Dr. Spitz is Assistant Professor of Psychiatry. Dr. Shapiro is also Staff Psychiatrist, Veterans Administration Hospital, Montrose, N.Y. Address reprint requests to Dr. Shapiro at PO Box 307, Scarborough, N.Y. 10510.

ciates (10–12) typifies current efforts to clarify etiologic factors in narcolepsy and sleep paralysis.

EEGs of patients with narcolepsy performed outside a sleep laboratory are usually within normal limits. With continuous recording, however, the EEG may show various diagnostic changes (13–15), depending on whether the patient has REM or NREM narcolepsy. In many patients the sleep attack is associated with a loss of muscle tone called cataplexy. Cataplexy, which is the most common of three auxiliary symptoms of narcolepsy, occurs in approximately 70% of patients (16). Laughter and anger are the most frequent emotional precipitants of cataplexy. Another auxiliary symptom, hypnagogic hallucinations, occurs in about 25% of patients (17). The least common of the narcoleptic symptom tetrad is sleep paralysis—a condition in which the patient may feel completely paralyzed for as long as 20 minutes during the transitions between wakefulness and sleep. Interestingly enough, sleep paralysis is often overcome if the patient is touched by another person.

In the majority of narcoleptic patients sleep attacks are associated with a shift from wakefulness to REM-stage sleep without the usual intervening stages. It is generally thought that the cataplectic episode is due to a failure to normally suppress direct entry into REM sleep from the waking state (18).

APPARENT PSYCHIATRIC PRESENTATION

Clinicians encountering a patient with one of the auxiliary symptoms of narcolepsy may think that he or she is suffering from a primary psychiatric disorder, especially if the patient does not spontaneously give an adequate history of sleep attacks. A patient's or family's description of cataplexy might seem at first to be a manifestation of hysteria, conversion reaction, depression, catatonia, or other psychiatric illness. As Pincus and Tucker stated, "These patients often fall asleep under boring social circumstances conducive to sleep. This is often misunderstood and the patients are considered lazy, impolite, neurotic, or worse" (16). The experience of listening to a narcoleptic patient describe vivid hypnagogic hallucinations is striking, since he may recount his interactions with people and objects in much the same way that a psychotic patient describes hallucinated experiences.

Narcoleptic patients at mental health clinics or psychiatrists' offices are frequently diagnosed as having a psychiatric disorder and treated accordingly. The following clinical vignette illustrates some of the potential pitfalls in the diagnosis and treatment of the narcoleptic patient.

CASE REPORT

The patient, a 42-year-old woman, first came to the mental hygiene clinic in October 1971, complaining of "seeing people in my room" and "hearing voices from out of this world." The examiner noted flat affect, hallucinations, and difficulty sleeping, and the patient was given the diagnosis of chronic undifferentiated schizophrenia. She was medicated with 2 mg of trifluoperazine orally three times a day and 100 mg of chlorpromazine orally at bedtime.

The patient seemed to improve and in November 1971 stated, "I just want you to sign for my medicine, I don't want to see you for anything more cause I'm getting along all right." She added, "I have trouble sleeping—every night I see my mother and she's dead." At this point another observer noted the presence of hypnagogic hallucinations and diagnosed the patient as having no mental disorder. She was then discharged with a diagnosis of latent schizophrenia and advised to return to the clinic if more symptoms developed. She did not return to the mental hygiene clinic, in spite of the recurrence of her presenting symptoms. Instead she continued to see a physician in the medical clinic for multiple medical problems.

In January 1975, the patient again entered the mental health clinic complaining of "pains in the head" and nervousness. She spoke of her persistent trouble sleeping and the "veil over my eyes seeing ghosts ever since I was born." She reiterated the problem of hearing voices and having nightly visits from her mother. This confused her even more because her mother had died in 1964. She related the head pains and nervousness to the death of her mother.

At this intake the patient was described as having a disorder that might be "compatible with culturally determined hysteria," but was officially diagnosed as suffering from chronic undifferentiated schizophrenia and was referred within the clinic for neuroleptic therapy. Her hospital chart indicated a consensus that she was a schizophrenic who experienced delusional and hallucinatory states.

Upon referral for pharmacotherapy the patient vividly described seeing her dead mother. She said, "My mother visits me every night, she comes into my room and she bothers me." Further history revealed that the patient *only* saw her mother when she was drowsy or falling asleep and *never* when she felt alert. A mental status examination demonstrated a range of appropriate affective responses, no signs of formal thought disorder, and no signs of clinical affective illness. She was oriented to time, place, and person, and her judgment was intact. There was no evidence of memory loss.

Neuroleptic medication was discontinued, the patient was sent for an EEG, and was given 30 mg of flurazepam orally at bedtime. She was instructed to return in 1 week. The next visit was rather dramatic. She entered the room and said "I just don't see or hear my mother at night anymore." She seemed grateful and cheerful and claimed that the medication had helped her. At this point it was clear that the patient's nightly "visits from her mother" were not necessarily the product of psychosis but vividly recalled hypnagogic states. These phenomena, along with disordered sleep, were thought to be a manifestation of a primary sleep disorder (narcolepsy). A more detailed history revealed that the patient had experienced daily episodes of irresistible urges to sleep for as long as she could remember. At times she would fall down asleep during the day, usually escaping injury by grabbing onto a chair or couch. At the onset of these sleep attacks she often heard voices and saw people. Many years before, when she was first frightened by these experiences, her father had explained them in terms of "spirits."

The patient's medical status included cardiovascular and metabolic conditions that precluded the use of the usual REM-suppressant medications (i.e., stimulants, tricyclic antidepressants, monoamine oxidase inhibitors, or strong

hypnotics), and treatment with flurazepam was maintained. In addition the patient began a program of reeducation about her illness and was placed in a weekly outpatient psychotherapy group. Her EEG was within normal limits.

At the time of this writing the patient has been on this regimen for more than 6 months. She has had few nocturnal hypnagogic experiences and the frequency of daytime auxiliary symptoms has been reduced markedly. She understands the nature of her symptoms and fears them less. She has attended group meetings regularly. A major theme in psychotherapy has been the effect on her life of years of being considered mentally ill. The patient is presently continuing in treatment in an effort to cope with her remaining difficulties.

DISCUSSION

This case history typifies problems encountered by the narcoleptic patient with auxiliary phenomena, who often describes hallucinations and is then rapidly given a psychiatric diagnosis. The maxim that hallucinations are not pathognomonic of schizophrenia (19) is often overlooked. In the case of sleep disorders this is of particular importance since hallucinatory experiences are frequently reported.

Physicians are taught early in their training that the clinician who does not remind himself about the existence of a disease entity will be unlikely to correctly diagnose that disorder. The psychologically minded clinician who has little contact with sleep disorders is a prime candidate for misdiagnosing narcoleptic patients. The deleterious effects of misdiagnosis are evident on several levels. Obviously, the choice of pharmacologic and/or psychotherapeutic treatment hinges upon diagnosis. Of equal importance are the social and characterological effects on an individual who is inappropriately labeled as seriously mentally ill.

A great deal of psychiatric literature has been concerned with accuracy in the diagnosis of mental illness, but there are still many patients who receive, for example, a diagnosis of both schizophrenia *and* major affective illness. Until questions of etiology are made clearer we must understand and expect such difficulties. However, some diagnostic dilemmas are avoidable. Differentiating between narcolepsy and schizophrenia or other psychoses is a case in point. Misdiagnosis can be avoided by the clinician's awareness of sleep disorders and by careful attention to the routine taking of a detailed history of the patient's present illness.

Characteristics of "Erotic" Practitioners

BY SHELDON H. KARDENER, M.D., MARIELLE FULLER, AND IVAN N. MENSH, PH.D.

Using the responses of 460 physicians to a questionnaire survey regarding sexual contact with patients (1), the authors attempt to statistically differentiate two groups—erotic practitioners and nonerotic practitioners. Analysis of data suggests that the freer a physician is with nonerotic contact with patients, the more statistically likely he is to engage in erotic contact.

A PREVIOUSLY PUBLISHED report (1) presented the results of a survey undertaken to determine the attitudes and behaviors of male physicians in five specialties regarding erotic and nonerotic behaviors with their patients. The purpose of this paper is to report data derived from a comparison of responses of the 59 physicians who acknowledged sexual contact with their patients and the 401 physicians who specifically denied any such contact. The full details of the overall study (1) and the philosophical and psychodynamic considerations of physicians engaging in sexual relationships with their patients (2) have already been published.

The analysis of the data comparing the two groups—erotic practitioners (EP) and nonerotic practitioners (NEP)—will be presented in terms of objective numerical responses and subjective "fill-in" statements.

DATA

In the EP group (N=59), the percentages of the total respondents from each specialty were as follows: psychiatrists, 10% (N=12); surgeons, 10% (N=7); obstetrician-gynecologists, 18% (N=15); internists, 12% (N=11); and general practitioners, 13% (N=14). There were no statistically significant differences between the EP and NEP groups regarding specialty, age, years in practice, marital status, years married, number of marriages, or the responses to the question, "Do you attempt to treat sexual problems in your medical practice?"

However, the responses to the following series of questions regarding nonerotic behaviors with patients served to differentiate the EP and NEP groups: "Do you believe *nonerotic* hugging, kissing, affectionate touching of patients may be beneficial?" ($p<.01$); "Do you engage in such practices?" ($p<.01$); "How often is this [nonerotic behavior] initiated by you?" ($p<.01$); "How often is this initiated by the patient?" ($p<.02$); "How often is this mutually initiated?" ($p<.01$); and "Do you believe such [nonerotic] behavior might be misunderstood?" ($p<.01$). Similarly, there was a statistically significant difference ($p<.01$) in the subjective responses to the question, "Under what circumstances might such behavior be utilized in treatment?" Responses to a similar series of questions regarding erotic contact with patients resulted in statistically significant differences, but these are not relevant since, by definition, these questions served to differentiate the two groups.

Because of the sensitive nature of this subject, it is particularly important to present the subjective response data provided by the EP and NEP groups for two questions—"Under what circumstances would nonerotic behavior with patients be beneficial?" and "Under what circumstances would erotic behavior be beneficial?"

There were 246 responses to the question on benefit of nonerotic contact—37 from the EP and 209 from the NEP group. The polarity of the groups became immediately apparent when their written comments were reviewed, but there was some overlapping. The NEP group responses ranged from "never" to "very conservative," whereas the EP group's responses ranged from "conservative" to "very liberal." The overlap, of course, occurred with the responses characterized as "conservative." Some of the comments from the NEP group included "never beneficial," "I can't think of any reason," "would contaminate the professional relationship," "never by the doctor though all right if the patient initiates," "no more than a handshake, perhaps," "when there is severe emotional trauma as in learning of a fatal disease or the death of a loved one," "elderly patients," "children only," "never kissing or hugging," "60-plus females maybe," "extreme circumstances," "extreme depression," "to let the patient know you want to be of help," "hold a hand at most," "if there has been a disaster or catastrophe,"

Dr. Kardener is Adjunct Associate Professor, Ms. Fuller is Research Associate, and Dr. Mensh is Professor of Medical Psychology, Department of Psychiatry, School of Medicine, University of California at Los Angeles, Los Angeles, Calif. 90024.

Computer assistance for this work was obtained from the Health Sciences Computing Facility at the University of California at Los Angeles, which is funded by grant RR-3 from the National Institutes of Health Division of Research Resources.

"severely withdrawn, isolated patient," "touching a shoulder to show reassurance," and "certain psychotic patients (who are out of touch)."

The EP group's comments paralleled some of the NEP group's comments except for the absence of any injunctions regarding nonerotic contact. Furthermore, the EP group made several "liberal" statements: "to provide reassurance [whenever necessary]," "to show support and acceptance," "whenever appropriate," "laying on of hands," "attempt to facilitate [therapy]," "attempt to encourage flowing [sic] with the here and now," "helps feelings of loneliness," "for [greater] rapport," and "when patients leave after long-term treatment."

There were 221 responses to the second question, "Under what circumstances might erotic contact with a patient be beneficial?", 31 from the EP group and 184 from the NEP group. There was absolute unanimity in the comments by the NEP group, all of whom stated at the very least that erotic contact was never beneficial. Many condemned such behavior, e.g., "represents ignorance or exploitation on the part of the doctor," "any doctor who can't control his emotions is unqualified," "appalling to contemplate," "any doctor who does needs therapy," "destroys relationship," "very sick behavior," "doesn't belong in therapy," "pelvic exams are hazardous enough," "any doctor who does is treating himself—not his patients," "evidence of psychosis in the doctor," "unethical," "unthinkable," "might be fun, but never therapy," and "might be all right for psychiatrists but never for doctors."

In contrast, the EP group provided the following responses: "demonstrates doctor's effectiveness to his patient," "supports and reinforces a patient's sexual appeal," "stimulating the clitoris helps a patient relax," "with friends who coincidentally happen to be patients," "it's OK since I'm not a doctor, I'm a therapist," "with mature patients," "it was originally for my need, but led to better rapport and more durable relationship," "when the patient ceased to be a patient," "with consent if a patient is over 21," "with consent but not in the office," "for teaching purposes," and "the intercourse was made part of the therapy."

It is particularly noteworthy that many of the responses from the EP group either condemned the practice or acknowledged it was not of benefit. For example, "(it's) never therapy," "might lose license," "never beneficial," "severs the relationship," "occupational hazard," "ended the relationship because the patient felt too guilty," "leads to harmful relationship," "it happens but is an error," "inexcusable," and "I told the patient not to return (afterward)."

DISCUSSION

The data indicate that no differentiation could be made in demographic variables between those physicians who engage in erotic behavior with their patients and those who do not. Nor does the physician's qualifications for specifically treating sexual problems distinguish these two groups. It is singularly the physicians' attitudes and practices regarding *nonerotic* behavior with patients that distinguish those who would also engage in erotic behavior. It would appear that the freer a physician is with nonerotic contact, the more statistically likely he is to also engage in erotic practices with his patient.

In a 1931 exchange of letters with Ferenczi, Freud discussed the danger of engaging nonerotically with a patient (3). Specifically, he was concerned that, while Ferenczi might be able to confine his physical contact with a patient to the nonerotic sphere, the advocacy of such practices would readily lead to both a relaxation and extension of proper limits. The danger of an "anything goes" ethic easily could be the result. The data presented in this paper tend to support Freud's hypothesis and underscore his concerns.

Self-Induced Depersonalization Syndrome

BY RAYMOND B. KENNEDY, JR., M.D.

The author reports two cases in which depersonalization occurred during the waking consciousness of individuals who had engaged in meditative techniques designed to alter consciousness. Psychiatrists should be aware of this phenomenon, as the number of organizations in the "consciousness movement" is increasing, and should ask people manifesting depersonalization about any involvement in activities leading to altered states of consciousness. In some cases it might be appropriate to refer such patients to responsible groups that teach altered consciousness by meditation as an ego-syntonic desirable state. The author cautions against the use of phenothiazines in cases where depersonalization is a prominent feature.

OF LATE, we have witnessed a burgeoning of groups that have alteration of the consciousness of their members as one of their primary goals. These groups employ many and varied techniques and range in accessibility from such highly publicized and scientifically researched organizations as Transcendental Meditation to obscure and esoteric organizations that operate completely out of view of the general public but nevertheless have substantial memberships. Some of these organizations claim to require of their members no more than 20 minutes twice a day, while others require a total life commitment. I consider this new movement aimed at the physiological alteration of consciousness (as opposed to the pharmacological alteration of the sixties and early seventies) to be one of the most important events on the contemporary scene, and I think it will undoubtedly have effects throughout the fields of psychology and psychiatry. At present, we as a profession seem to be paying this movement little mind.

The following two cases represent one of the epiphenomena from the consciousness movement.

CASE REPORTS

Case 1. A successful 37-year-old businessman became curious about yoga and different means of increasing self-awareness. One evening, while alone, he conducted a series of exercises described in a book called *Awareness* (1).

During a breathing exercise, he experienced a feeling of being outside of his body looking down on himself. Frightened by this feeling, he terminated his experiment, but he tried it again later that evening with the same results. Over the next few days, he tried several such experiments but stopped when strange experiences began to occur spontaneously and uncontrollably. He felt at times that either he was not real or that his surroundings were not real. After he saw a double image of himself in a mirror, he sought admission to a local hospital, where he was treated with tranquilizers and released. He sought readmission a few days later in a state of panic because the tranquilizers he had been given (he did not recall the name) seemed to increase his feelings of unreality.

ECT was proposed to him but he refused, left the hospital, and on the advice of a friend sought help from a long-time practitioner of yoga. He stayed with this yoga instructor for several days and then was able to return to work, feeling that he had gained enough insight into the occurrences that he was no longer bothered by them.

I saw and interviewed this man when he came to visit an Indian yogi and guru whom I was studying and studying with. He had been told by his first yoga instructor that he should visit this particular yogi because he had had "many and great experiences that will be of great benefit to you."

When I interviewed him, approximately 16 months had passed since the first depersonalization episode; although he continued to have intermittent episodes consisting primarily of autoscopy (feeling of looking down on oneself from above) and double mirror images, he now experienced these as ego-syntonic and was able to carry on his routine business activities without interruption. He was well-groomed and dressed like a businessman in coat and tie. His affect was appropriate, his associations were tight, and there was no evidence of maladaptive behavior or thinking. He was warmly received by the yogi (Swami Maktananda), who seemed intuitively to know of his situation. The Swami told him that such experiences sometimes occur in one's *sadhana* (spiritual practices) and admonished him never to go to a hospital again and under no circumstances to have "shock treatment."

Case 2. A 24-year-old man went to a mental health center with complaints of increasingly frequent episodes of feeling that things around him were unreal, alternating with periods in which he himself felt unreal. The episodes had begun 18–24 months earlier and had not caused him great alarm at first, but later he became unable to maintain employment because of them. He mentioned further episodes in which the sidewalk appeared to disintegrate beneath his feet. The psychiatrist who originally saw him was concerned that this might represent an organic brain lesion and obtained an EEG, brain scan, skull films, and EMI scan, all of which were normal.

Upon my initial contact with this individual, I noted a small pin on his lapel denoting his membership in Arica Insti-

When this work was done, Dr. Kennedy was a resident at the University of California, Los Angeles, Neuropsychiatric Institute. He is now in private practice at 990 West Fremont St., Suite E, Sunnyvale, Calif. 94087.

tute. I learned that he had belonged to this organization for approximately 24 months and that, although he was not currently an active member, he performed various Arica meditation exercises almost daily, occasionally for several hours at a time. After gaining some trust in me, he confided that some of the episodes he experienced represented to him a sort of fusion with the cosmos. At first he had been pleased with his ability to induce this state, but these occurrences now caused him anxiety because he was unable to control them and as a result could not hold employment. Further interviews revealed a complex social interaction between him, his wife, and another woman, and the fact that he had initially sought therapy at least in part to obtain financial assistance, which no doubt led to some exaggeration of his symptoms. After a few sessions he became calmer and was able to resume gainful employment.

It should be noted that during his evaluation he was seen by two psychiatrists, a neurologist, and two other experienced mental health professionals, none of whom thought he showed any signs of schizophrenia. Although this patient had taken LSD in the past, he had not taken any psychedelic drugs (including marijuana) for approximately 1 year.

DISCUSSION

Both of these cases have as their common feature what is referred to in psychiatric terminology as depersonalization and derealization. Depersonalization may occur in a wide variety of syndromes, including schizophrenia, various drug states (e.g., LSD intoxication and phenothiazine therapy), encephalitis, epilepsy, hysteria, manic-depressive disorders, virtually all of the neuroses (2), and even in 39–70% of the so-called normal population at one time or another (3). A chronic relapsing form of depersonalization not associated with other mental disorders and not part of a situational reaction was afforded a place of its own in the psychiatric nosology in *DSM-II* (4).

It is fairly well known that out-of-body states may occur in mystics during the trance state induced by various meditative techniques. However, to my knowledge it has not been reported that milder depersonalization and derealization states are often encountered in practitioners of meditative techniques during normal waking consciousness.

I recently interviewed a random sample of 23 students of yoga and meditation, and all but 1 told of intermittent episodes that could be classified as mild to moderate depersonalization and/or derealization. These ranged from frank out-of-body states lasting for periods of almost one hour to secondary "flashes" and feelings of altered reality, all during full waking consciousness. Most of these experiences took the form of feelings of unreality or altered reality lasting a few seconds and occurring most commonly in the presence of the meditation teacher. None of these individuals considered the occurrences to be abnormal in any way.

In casual conversation with members of other groups, I have heard several reports of similar phenomena. Actually, one might expect this since, as Sedman (3) points out, depersonalization occurs under circumstances of either altered emotions or altered consciousness, and altered consciousness is the goal of meditators. In a classical paper on depersonalization, Schilder (5) stated that such phenomena tend to occur in people who are preoccupied with self-observation and who have detached libido both from the external environment and the ego, or at least certain parts of the ego. Schilder spoke of a "criticizing and scrutinizing element of the personality which has abstracted to itself the full libido" as the observing element in the self-observation. This situation of self-observation and decathected external environment and ego is exactly what many of the consciousness-movement schools teach in their endeavor to realize the ancient maxim "know thyself" and to disengage themselves from the *maya* (illusion) of everyday life and of their "false ego." The difference between Schilder's patients and the meditators is that in the latter group the part that is observing is nonjudgmental and neutral. The other major difference between those with the psychiatric syndrome and those who voluntarily induce similar states is that the depersonalization of "self-inducers" is ego-syntonic and viewed as part of the state they are seeking.

The first individual described in this paper was frightened only until he found someone to reassure him. This reassurance apparently transformed the previously frightening episodes into ego-syntonic occurrences. The second individual had previously been a member of Arica, a group that, according to its founder and leader, is dedicated to ego destruction (6), but he was no longer actively involved with this group. His reasons for coming to therapy were mixed and his anxiety about his depersonalization states was exaggerated, but he experienced some anxiety and appeared unaware that his meditative practices were contributing to these states until the therapist pointed this out.

The intriguing aspect of this is that apparently by using virtually the same mental maneuvers a syndrome may be produced that, depending on the attitude the person adopts toward himself and then toward the resulting phenomenon, may be experienced either as something to be sought and valued or as something to be feared and called a disease. Perhaps what we need to do with patients who exhibit primarily a depersonalization syndrome is to teach them first to accept themselves uncritically and second to accept their depersonalization. Individuals who observe nonjudgmentally do not describe their altered perceptions as flat or devoid of color but as exhibiting increased color.

CONCLUSIONS

It is likely that we will see an increasing number of psychiatric casualties among individuals who seek to alter their consciousness as these practices become more widespread. These casualties will no doubt be more likely to occur outside a supportive group set-

ting, but some may occur within the groups themselves, especially as the number of such groups grows and more inherently disturbed individuals are attracted to groups with incompetent leaders. Depersonalization is one of the ways in which such casualties may manifest themselves. As psychiatrists we need to be aware that depersonalization may be self-induced. We should not neglect to ask our patients about practices that might induce or contribute to such states. As the first case I described illustrates, it might even be wise in some instances to refer such patients to particular groups, some of which are extremely reliable and in my experience are far more likely to exert a positive than a negative influence in the individual's life. Certainly, this seems a better alternative than ECT, and if such a suggestion is made by the psychiatrist, it is more likely that the individual may remain in therapy long enough to deal with any underlying pathological causes than if he finds such a group on his own. Finally, it is worth emphasizing that the phenothiazines have been reported both to cause depersonalization and to increase depersonalization in those already suffering from this symptom (3), as was probably the case with the first patient I described. Phenothiazines are therefore contraindicated when depersonalization is a prominent symptom.

The Why of Fragging

BY THOMAS C. BOND, M.D.

The author studied 28 men convicted and confined for use of explosives in assaults on superior officers during the Viet Nam war. There were several predominant characteristics in this group, including deprivation and/or brutality in family backgrounds, poor self-image, lack of critical self-observation, the use of externalization, and feelings of insecurity or vulnerability. Drug use joined with these and several other factors related to the situation of these men in Viet Nam in a lethal combination that led to the perpetration of an indirect assault with an explosive device on a figure perceived as powerful and threatening.

OVER THE past decade, there has been an increase in the frequency of criminal use of explosives by various political groups attempting to popularize idiosyncratic views or to promote terrorism. In most instances, the targets are either property with some special significance or random individuals who are attacked in order to promote an atmosphere of fear and disorder.

The use of explosives against specific individuals is rare outside of organized crime and military combat. During the Viet Nam war, there was an upsurge of a unique type of explosive use directed by troops toward their own superior officers rather than the enemy. This form of assault became popularly known as "fragging" because of the frequent use of the fragmentation grenade. The unique nature of this phenomenon lies not so much in the choice of superiors as targets but rather in the frequency of its occurrence and the type of weapons employed. In previous wars, assaults on superiors were far less frequent. One reporter has stated,

> In World War I, which involved over 4,700,000 American military, fewer than 370 cases of violence directed at superiors were brought to courtmartial. This low ratio was fairly consistent through World War II and the Korean police action. It did not change significantly until Vietnam. (1, p. 12)

When this work was done, the author was Chief, Psychiatry Division, Directorate of Mental Hygiene, U.S. Disciplinary Barracks, Fort Leavenworth, Kans. He is currently Instructor in Psychiatry, Harvard Medical School, and Assistant Psychiatrist, McLean Hospital, Belmont, Mass. 02178.

Between 1969 and 1972, there were almost 800 recorded incidents of the use of explosive devices against superior officers. The phenomenon reached a peak in 1971, when the rate was 1.8 assaults per 1,000 servicemen in Viet Nam. These statistics reflect only assaults with explosives and do not include assaults with weapons such as guns and knives.

The scope of this activity was unprecedented, but an even more unusual factor was the specific nature of the attack. Whereas previous assaults generally involved some direct confrontation, albeit at a distance, fragging was indirect and involved no face-to-face confrontation. This fact raises interesting questions regarding the psychological makeup and motivations of the individuals involved.

It is often quite difficult to identify the perpetrators of such assaults, but we were able to interview in prison a group of men convicted of this offense. The findings of this study have been described in detail elsewhere (2); I will present a summary and conclusions here.

THE SAMPLE POPULATION

The sample consisted of 28 men who had been convicted by court-martial of using explosive devices in an assault on a superior officer while on active duty. The overwhelming majority of these assaults occurred in Viet Nam. On the average, the men were 20 years old, had served about 28 months on active duty, and 26 of the 28 had enlisted rather than having been drafted. Six of the 28 men were black.

The men reported a feeling of being scapegoated, i.e., "singled out" from their peers by command for restrictions and punishment. They were generally dissatisfied with their job assignments; many had enlisted for a particular skill and were then asked to perform unrelated jobs in which they had no prior training. The majority were assigned to support units rather than fighting units and were not in direct combat situations at the time of the assault.

NATURE OF THE ASSAULTS

The actual assaults occurred at night, most within less than 24 hours of initial intent. The actual planning or premeditation seemed to consist primarily in talking with others about intent, as if to build courage or gain support, and then using intoxicants (drugs or alcohol) to overcome any final inhibitions. The vast majority (87.5%) reported being intoxicated (on a wide variety of substances) at the time of the assault. It is also interesting to note that two-thirds of these men reported they had done nothing to avoid being caught.

Soldiers in Viet Nam had developed a macabre ritual whereby potential victims of fragging were often warned anonymously that they could expect retaliation if they did not change their mode of behavior. "Bounties," in the form of cash donations, were often pooled by the soldiers in a specific unit to be paid to the man who carried out the final assault. This bounty system was designed to intimidate officers; therefore it was essential the officer be informed of the situation. Although many of the victims of the offenders we studied had been warned, the attacker rarely had done the warning. Only one man in this sample reported that there had been a bounty on his victim; he said that this played no part in his final action.

The choice of the victim reflected the command structure on the unit level—captains and first sergeants were the predominant targets. On the company level, the captain is primarily responsible for disciplinary action, promotions, and transfers, and is the highest ranking authority with whom these men had contact. The first sergeant is responsible for work details, passes, and recommendations to the captain for various forms of action. Thus, in essence, the victims were those held to be most responsible for the offender's predicament.

In terms of precipitants for the action, 75% of the sample reported some disagreement with the victim or victims, either verbal or physical, and almost 90% of these took action within 3 days of the altercation. The victims were seen as having deprived the offender of something he wanted (e.g., promotion, discharge, transfer, or drugs) and were further perceived to be a threat and a danger to the offenders—either physically or psychologically, or through their incompetence.

Two factors that did not prove to be significant were racial tension and political activism. The first factor should be qualified in that only 4 of the 24 men personally interviewed were black, and 2 of them felt race was a factor in the offense. With regard to political activism, the men generally seemed apolitical; most had enlisted in the service and supported the war effort. Further, most of them were loners and not given to participating in idealistic causes.

PSYCHOLOGICAL FACTORS

The offenders' backgrounds involved parental separations and brutality, poor performance in school situations (only 5 had graduated from high school), no viable marriages, and previous incidents of lesser forms of antisocial behavior. These men had experienced rejection and disappointment throughout their lives and demonstrated a low tolerance for frustration when their underlying dependency needs were not met. They were largely loners, having few friends, and often expressed feelings of inadequacy and anxiety in groups. These men viewed enlisting in the Army either as a way of escaping from problems at home that they were unable to resolve or an attempt to prove their masculinity and independence. When the military failed to meet their expectations, they became more despondent, focusing the reasons for this failure on external authority figures. The very fact that only 2 men in the sample had been drafted would support the view

that these men were seeking something in the military that they could never attain on their own.

The situation in which they found themselves in Viet Nam certainly contributed to their offenses. In combat areas, violence and assault are not only commonplace but also encouraged. Weapons are generally easily available, and the social inhibitions against their use that exist in communities at home disappear in a hostile environment. Further, the prevalence and openness with which the assault of superiors was discussed by the troops provided an atmosphere that approached positive sanction for such actions. In the support units to which most of these men were assigned, they were faced with boredom and monotony, with few or no means of relief. This inactivity created dysphoric feelings and frustration in these men, who relied on external factors for stimulation, which led to anger and rebellion. Another factor was that these men often had little job satisfaction because they had been assigned to positions for which they had not been specifically trained.

The sense of vulnerability reflected in the histories of these men and in the nature of their offenses is quite striking. Such factors as parental neglect and brutality, inadequate peer relationships, and failures in structured school situations combined with these men's stated reasons for enlistment reflect poor self-image and problems of self-sufficiency. Also indicative of feelings of inadequacy were their perception of the victim as a threat, their failure to warn the victims, despite the fact that others had, the belief that they had been scapegoated and singled out, and their need to discuss their intent with peers before the incident. Their fear of direct contact with a figure perceived as powerful is shown in the fact that these assaults were carried out under cover of darkness and without face-to-face contact. Finally, the choice of a weapon that is a powerful annihilating force would appeal to a person who perceives himself as powerless and inadequate.

Characteristically, these men chose to externalize their difficulties and to focus on others as being responsible for their failures. They did not acknowledge that their behavior might have invited the punitive actions from superiors that led them to feel scapegoated. They were disappointed in the military and felt that their immediate superiors had deprived them of something. Their peers reinforced these ideas but were able to limit their own expressions of discomfort to verbalizations. It is interesting that two-thirds of these men did nothing to avoid being caught, almost as if all of their problems could be solved if their perceived nemesis could be destroyed. They lacked feelings of remorse after the event since they had little insight into their own behavior.

THE LETHAL COMBINATION

The factors I have mentioned thus far were not unique to the Viet Nam war and thus do not totally explain the unprecedented frequency of fragging during this conflict. One factor that was unique to Viet Nam was the wide availability and use of a variety of drugs—in no previous war had drug use been so prevalent and pervasive. The combination of drugs and the specific personality factors of these men seems to be the most striking and significant finding. The readily accessible drugs provided an easy albeit temporary escape from daily anxieties and problems of adjustment for these men, who had few inner resources and sought stimulation in the external world through their drug use. Drugs were also a form of rebellion against superiors, but conflicts were created by threatened loss of availability and disciplinary action for their continued use. The officer was a threat to these men because he had the power to remove their means of escape and relief of anxiety.

All of the men in the sample reported using a wide variety of drugs with no discernible pattern, and 87.5% reported being acutely intoxicated at the time of the incident. It seems clear that drugs were essential factors in the assaults; they alleviated whatever anxieties or inhibitions the men had about committing the assault. The indirect assault seemed a way to obtain greater self-esteem and acceptance by a peer group of men who were largely loners, and the choice of this mode of attack avoided direct confrontation with an authority figure perceived as powerful.

CONCLUSIONS

One should always avoid extrapolation from this type of study on too large a scale. The sample consisted of men who had been convicted and confined for such assaults on superiors; obviously, given the overall incidence of fragging, they represented only a small fraction of such offenders. The reasons why these men were identified when others were not probably represents an important variable.

Nevertheless, a study of this group can provide some insight into the nature of individuals who would choose to perpetrate such assaults. These were men who had suffered brutality and separation from parents, who demonstrated difficulties with interpersonal relationships, and who endured deep feelings of insecurity and vulnerability. They externalized their problems to authority figures and had little ability to evaluate their own behavior objectively. The use of drugs alleviated some inner anxieties and enabled them eventually to assault a perceived enemy, yet they could not face the situation directly. Indirect assault with a powerful weapon became an easy alternative.

Although some drugs (e.g., amphetamines, alcohol, and occasionally hallucinogens) are reported to promote aggressive behavior, other drugs these men used do not (e.g., barbiturates, opiates). The drugs used were frequently taken in varied combinations and no discernible pattern was evident. What seems evident

from this study is that a wide variety of substances may act to relieve inhibitions and allow underlying aggressive impulses to surface. However, some inhibitions remain and this probably accounts for the indirect nature of the assaults.

Occurrence of Psychiatric Disorder in a County Jail Population

BY GLENN E. SWANK, M.D., AND DARRYL WINER, M.A.

The authors report on a year's experience in providing psychiatric services in a county jail setting. Of 545 inmates evaluated, 22% were diagnosed as psychotic and 23% had a history of long-term or multiple hospitalizations. The authors discuss the implications of these data in terms of the problem of providing adequate psychiatric care for such a population.

THIS PAPER reports on 1 year's experience in providing psychiatric services to the inmates of Denver County Jail in Denver, Colo. By arrangement with the Northwest Denver Community Mental Health Center, also in Denver, psychiatric services were provided to the jail beginning in June 1974. This arrangement was funded by a grant[1] from the Colorado Division of Criminal Justice. Staffing consisted essentially of a half-time psychiatrist (G.E.S.), who was funded under the grant, and a part-time psychologist (D.W.), who worked on a volunteer basis. The goals of the program under the grant stressed diagnostic and referral services and crisis-intervention activities. During the year under study, we gathered data on the inmates' psychiatric histories and diagnoses.

THE FACILITY

The Denver County Jail is a large (capacity of 708 inmates), relatively modern (completed in 1956) facility serving the city and county of Denver, a geographically unitary municipality and county area with a population of approximately 574,000 (1). All persons (except juveniles 17 years of age or younger, who are under the jurisdiction of Denver County Juvenile Court) who are detained past an initial 24- to 48-hour holding period in the Denver City Jail are placed in the Denver County Jail. In addition to these persons, who are charged with a variety of offenses, those who are sentenced for up to 1 year on relatively minor (misdemeanor) offenses serve their sentences here. Those convicted on more serious (felony) charges are transferred to other institutions to serve their sentences.

In 1973, the latest year for which statistics are available, 12,453 persons (excluding those charged with public intoxication under a then existing statute) entered the jail (2). Of this number, 2,875 were serving misdemeanor sentences, 2,994 were awaiting trial on misdemeanor charges, and 2,506 were awaiting trial on felony charges. The rest consisted of federal prisoners in transit and so forth. There was a considerable overlap between the two groups of misdemeanants, since the majority of those serving misdemeanor sentences derived from those awaiting trial on misdemeanor charges. At the time of this study the average daily population of the jail was 550 inmates.

The jail had a 24-hour medical infirmary, which was staffed by registered nurses with daily physician coverage and backed by the facilities of a large city and county hospital (Denver General Hospital) with a special police holding ward. Psychiatric consultation had been previously available through this hospital, and a part-time psychiatrist had been regularly assigned to the police holding ward.

THE SERVICES

In accordance with the grant providing for psychiatric services at the jail, the psychiatrist and psycholo-

The authors are with the Northwest Denver Community Mental Health Center, West Eighth Ave. and Cherokee St., Denver, Colo. 80204, where Dr. Swank is Psychiatrist, Transitional Living Unit, and Mr. Winer is Evaluation Analyst, Program Evaluation Section.

[1]County Jail Diagnostic Services, Project 73-2C-(5)-C3-213, Colorado Division of Criminal Justice, State of Colorado.

gist, working as a team, engaged in the following activities:

1. Psychiatric diagnostic screening of as many jail inmates as possible. Inmates were seen for diagnostic evaluation upon the request of the medical or administrative staff of the jail, self-request by the inmate, or, when possible, routinely during classification procedures upon the inmates' entry into the jail. The inmates were evaluated by means of clinical interview.

2. Transfer of seriously mentally ill inmates to psychiatric treatment facilities when possible. In regard to inmates charged with relatively minor (misdemeanor) offenses, it was possible under state mental health statutes to arrange for transfer of jurisdiction from criminal courts to various psychiatric facilities in the area. However, for those inmates charged with more serious (felony) offenses, such direct transfer was not possible, although temporary hospital care was available through the police holding ward at Denver General Hospital. In addition, it was possible to recommend to the court involved that certain individuals be examined according to competency and criminal insanity statutes.

3. Treatment services at the jail as indicated, but with a particular emphasis on crisis intervention with suicidal inmates. Inmates who had threatened or attempted suicide were seen several times in brief, crisis-oriented psychotherapy. Other strategies included medication, transfer of inmates to other areas in the jail, intervention into various problems involving jail procedures, bonds, visitation, assignment of attorneys, and so forth.

DATA OBTAINED

During the year of our study, 445 inmates were seen by the team for psychiatric evaluation by way of referral or self-request. Obviously, these inmates represent a specially selected group (group 1). During the same period, 100 inmates were seen for psychiatric evaluation as they entered the jail in daily consignments. On these occasions all arriving inmates were seen, and hence this group (group 2) represents a more random sample. Table 1 presents the basic demographic and background data for the 2 groups. Table 2 presents information on psychiatric diagnosis by general category.

TABLE 1
Demographic and Background Data for Two Groups of Jail Inmates

Item	Group 1 (N=445)*		Group 2 (N=100)	
	Number	Percent	Number	Percent
Age (years)				
10–19	47	10.6	10	10.0

Other institution	5	1.1	0	0.0
Undetermined†	60	13.5	12	12.0

*For the categories of age and ethnic group the numbers total slightly less than 445 because of a recording error; for the category of marital status the numbers total less than 445 because of cessation of recording this category.
**Primarily unspecified nonmarital liaisons.
***Includes immigration prisoners, U.S. marshall's prisoners, and evasive respondents.
†Large number in this category is apparently due to respondent evasiveness.

DISCUSSION

The number of psychotic persons (table 2) encountered in the jail was striking, as was the number with a history of psychiatric hospitalization (table 1), particularly long-term (more than 1 month) or multiple hospitalizations. The difference between the 2 groups of inmates, of course, only suggests that the referral process is reasonably successful. It is believed that there has been a marked increase in the number of seriously mentally disturbed individuals entering the jail in recent years, but unfortunately there are no earlier data available for comparison. At any rate, the number of such individuals noted in the period under consideration appears to be problematic; it may be related to the present manner of handling chronic psychiatric patients. Under the prevailing mental health philosophy in this region, long-term psychiatric inpatient care is essentially unobtainable except as a result of criminal commitment.

Of the jail inmates with a history of long-term psychiatric hospitalization, many had been state mental hospital patients. From our attempts to arrange psychiatric hospitalization for such persons, it was apparent

that the criminal justice system was most receptive to this whenever it was possible and that the system seemed to have inherited responsibility for these persons by default rather than preference. However, we were unsuccessful in removing even the most severely psychotic individuals from the jail for any substantial period of time. Some individuals returned to the jail 4 or 5 times (not counted as separate evaluations) in spite of being released to a hospital on each occasion. We feel it is tragic that such numbers of severely mentally ill persons are being left to be dealt with by a jail rather than by the psychiatric community.

The Cessation of Marital Intercourse

BY JOHN N. EDWARDS, PH.D., AND ALAN BOOTH, PH.D.

The authors found that marital coitus had ceased for a definable period (median=8 weeks) in one-third of a sample of 144 men and 221 women who were relatively young and had been married an average of 11 years. An analysis of factors related to the social background and marital relationship of the respondents indicated that the cessation behavior of men is more highly predictable than that of women and that antecedents of this behavior differ markedly between the sexes. The authors suggest that, even among relatively young couples, marital intercourse is discontinous and problematic.

MARITAL INTERCOURSE is the only form of sexual behavior that is universally prescribed. All societies indicate that coitus between spouses is both a right and a duty (1). Since the presence and intensity of sexual activity is largely a function of the availability of a socially sanctioned partner, one would expect coitus in marriage to be relatively nonproblematic and very frequent in occurrence. However, a large body of literature—psychiatric, psychological, and sociological—attests to the fact that this is not the case. Problems abound, especially those of an individual nature, and the highest reported mean frequencies of marital intercourse (about 3 times a week among individuals 18–24 years old) are far below any theoretical limits (2).

Although the problematic character and relative infrequency of intercourse between spouses are clearly recognized in contemporary studies, certain aspects have been overlooked, e.g., the cessation of marital coitus, which has been investigated primarily in the elderly (3). Rather than being an abnormal phenomenon associated with, for example, chronic physical or mental illness or postpartum taboos, cessation of intercourse occurs in a sizable segment of the general married population, and marital intercourse, as our data

will indicate, tends to be discontinuous for a significant proportion of couples.

Several questions can be raised concerning this finding. What are the antecedents of cessation behavior? Is the discontinuance of intercourse related to an individual's social background, or is the more immediate marital relationship responsible? Do men and women differ in the incidence of reported discontinuance of marital intercourse? If so, do the same factors explain their behavior? And finally, to what do such individuals attribute the cessation of intercourse, and are the reasons given the same for men and women?

METHOD

Sample

The data in this study, which was conducted in 1973, come from a stratified probability sample of men and women in Toronto, Ont., Canada. The subjects were relatively young—2% were under 20, 74% were 20–39 years old, and 24% were over 40. The length of time married ranged from 1 year to more than 20 years, with a mean of 11 years.

All individuals interviewed were part of intact families of European or North American descent with one or more children. The wives in all families represented were under 45 years of age. The men and women were given a 2-hour field interview and a medical examination. At the close of the medical examination, the physicians, who had received extensive training in interview techniques, asked a series of questions regarding sexual behavior. A total of 221 women and 144 men, some of whom were married to each other (N=124), were interviewed and examined. A systematic comparison of the characteristics of those consenting to be both interviewed and examined, who comprised two-thirds of the original sample, with those who did not consent revealed that the two groups were similar with respect to occupational status, age of head of household, and length of residence in present dwelling. The major difference was that many of the nonrespondents had migrated from Western Europe.

Variables Examined

Cessation of intercourse. The physician interviewers asked whether intercourse between the respondent and his/her spouse had ever stopped for any reason other than pregnancy and, if so, why this had happened. These queries were followed by a question regarding the length of cessation.

Background variables. The background variables examined in this analysis were 1) age, 2) occupational status of the head of the household according to the Blishen Index (4), a standardized scoring system for the prestige rankings of Canadian occupations, 3) level of educational achievement, 4) ethnicity of respondent and spouse (i.e., Canadian born or not), 5) religion (Catholic or non-Catholic), 6) whether the respondent had resided in a large city (population of more than 500,000) as a child, and 7) current employment status of wife.

Marital variables. The marital variables included such demographic factors as number of years married, number of children, and whether the individual had ever been divorced.

Six attitudinal factors were explored. The first examined which partner dominated the pair. Respondents were asked, "When you disagree with your wife/husband, who gets their way?" The responses "husband always" or "husband mostly" were categorized as husband-dominated; comparable responses for the wife were coded as wife-dominated. Second, two items were used as a perceptual index of affection between the married persons: "My wife/husband is just as loving as she/he used to be" and "My wife/husband is more critical of me than she/he used to be." An "agree" response to the first item or a "disagree" response to the second was scored 1; other responses were scored zero. "Don't know" was treated as missing data in this and all other items. If a response to one or both questions indicated a decrement in love, the response was so coded. The number of disagreements between the spouses in the preceding 12 months was determined from an inventory of arguments involving family members. The initial question read, "In many households bad feelings, arguments, or fights occur from time to time. Do bad feelings, arguments, or fights ever arise in this household?" An affirmative response was followed by a detailed set of questions regarding the participants, frequency, and topics of arguments. Fourth, we determined whether either member of the pair had threatened to leave the other as an indicator of the quality of the couple's relationship. ("A lot of people have quarrels with their husband/wife and get so angry that they ask them to leave home or they threaten to leave home themselves. Has this ever happened in your marriage?")

The individual's general feeling of alienation was the fifth attitudinal variable, and the sixth was whether a lack of privacy in the home had recently prevented the respondent from having sexual intercourse.

Data Analysis

The impact of the background and marital variables on the dependent variable, cessation of marital intercourse, was examined by means of multiple regression. By entering one set of variables before the other, we are able to ascertain the unique variance explained by each set of variables as well as their shared variance. The standardized regression coefficient (beta) represents the effect each variable has on the dependent variable, cessation of coitus, with the effects of all other factors held constant. Within the sample, beta may be interpreted as a measure of the importance or usefulness of a variable in accounting for variation in the dependent variable (5). For example, a beta of .30 in this sample indicates a highly significant predictor of cessation and is twice as useful in accounting for cessation than a variable for which a beta of .15 is obtained.

RESULTS

One-third of the respondents (32% of the men, N=46, and 36% of the women, N=80) reported that they had ceased having intercourse with their spouse for some definable period. The median length of cessation was 8 weeks. It is immediately apparent from the data in table 1 that the behavior of men is better accounted for by the variables we examined than is that of women. As table 2 indicates, 23% of the total variance in the cessation behavior of men as opposed to 13% in women is explained by the background and marital variables.

The factors that best explain cessation clearly differ for men and women. For men, the background variables have a substantial effect on the tendency to stop having intercourse. Crucial background variables for men are recent emigration from Europe, being non-Catholic, and current lack of employment of the wife. On the basis of these data, the marital situation evidently has little impact on the man's decision to discontinue marital coitus.

The findings are just the opposite for women; their cessation behavior is most critically influenced by conditions of the marital relationship. In particular, the wife's perception that her husband is dominant in family decision making, her belief that he has become less affectionate, and the occurrence of threats to leave home were significantly related to cessation of intercourse.

The only common factor that explains discontinuance of sex for both men and women is a perceived lack of privacy. Whether the lack of privacy actually intervened or merely provided a convenient rationale for stopping the sexual relationship is open to debate. The evidence presented in table 3 on self-reported reasons for cessation appears, however, to support the latter interpretation.

The self-reported reasons for the cessation of marital intercourse were varied, but they tend to fall in the eight categories given in table 3: surgery (e.g., hernia repair, hysterectomy, cholecystectomy), illness (e.g., vaginitis, stroke, unspecified ailments), psychiatric impairment (e.g., depression, nervous breakdown, alcoholism), marital discord (e.g., angry at mate, spouse "playing around"), decreased sexual interest, menstruation, birth control procedure, and geographic separation (e.g., spouse working in different city, shift work, lack of privacy in the household). Obviously, the categories are not mutually exclusive or independent of causal linkages. For example, marital discord and lack of interest in sex may overlap, and psychiatric impairment may be a precursor or a consequence of marital discord. The categories merely represent the clusters into which the responses seem to fit without straining the meaning of the respondents' replies.

The reason given most often for cessation was marital discord. The importance of this variable is further highlighted by the fact that 52% of those who had stopped having intercourse for this reason also indicated that their spouse was less loving than he/she used to be, whereas only 30% of the individuals who reported cessation for some other reason gave this response. Following marital discord in terms of frequency were illness, decreased sexual interest, and surgery. It is noteworthy that the respondents who reported cessation because of a decreased interest in sex were an average of 3 years older than individuals who gave other reasons. Psychiatric impairment was the fifth most frequent reason given for cessation. In contrast to the analysis of background and marital variables, the self-reported reasons for cessation were quite similar for men and women.

Almost three-fourths of the individuals who attributed cessation of marital intercourse to decreased inter-

est in sex, birth control procedure, or geographic separation reported that the cessation had lasted 3 months or more. Sixty percent of those who cited psychiatric impairment reported lengthy cessation, followed by 46% in the surgery category, 30% for marital discord, and 16% who gave illness as the reason for having stopped intercourse. It is interesting to note that, as prominent as marital discord was in the other analyses, it ranked sixth in terms of the percentage of individuals within the eight categories who reported lengthy cessation.

SUMMARY AND CONCLUSIONS

One-third of this stratified sample of relatively young men and women who had been married for an average of only 11 years had ceased marital coitus for a definable period. Since the median length of cessation was 8 weeks, it seems that coitus may be highly discontinuous for many married couples.

The cessation behavior of men is more highly predictable than that of women in terms of factors related to social background and the marital relationship. Moreover, the background and marital variables that best explain sexual cessation differ markedly between the sexes: social background factors have a far more substantial effect on the tendency of men to cease intercourse than do factors related to the marital situation, whereas the reverse is true for women. Only a perceived lack of privacy is predictive of the cessation of intercourse for both men and women. It is interesting to note, however, that only small, nonsignificant differences were found between men and women with regard to self-reported causes of cessation of marital intercourse.

It appears, on the basis of these findings, that we need to reexamine the assumptions that are often made as to how efficacious the societal prescription of marital coitus is and what level of sexual activity may be considered as within a "normal" range. Assuming that the respondents in this study are representative (and, given our sampling techniques, there is no reason to question that they are not), discontinuous intercourse is an experience of a sizable proportion of the population and implies, at least under certain circumstances, that the obligatory nature of marital coitus is abrogated, sometimes for rather extensive periods of time. However, inasmuch as most of the self-reported reasons for cessation point to situations amenable to intervention, the findings also call into question our awareness of the situation and the remedial possibilities that exist. Certainly, psychiatric impairment and marital discord are obvious to practitioners. Discontinuous marital intercourse, whether it be cause or effect, should command greater attention.

Digit-Symbol Performance in Methadone-Treated Ex-Heroin Addicts

BY PHILIP W. APPEL, PH.D., AND NORMAN B. GORDON, PH.D.

The digit-symbol substitution task (DSST) of the WAIS was given to working (MW) and nonworking (MNW) patients on high-dose methadone maintenance and to two comparison groups to assess the function of attention in these patients. Mean DSST scores were significantly lower for the MNW group than for the other three groups, which did not differ. However, the scores for the MNW group were within the normal range. DSST scores and length of methadone treatment (range: 11 months to 8 years) were positively correlated, providing no evidence of deterioration with increasing duration of treatment.

INTEREST IN the attentional function of methadone patients, the focus of the present study, was stimulated by reports of drowsiness even after extended periods of maintenance. Mild sedative and tranquilizing effects have also been reported (1). Although methadone patients perform adequately on psychomotor and intellectual tasks (2), the available evidence suggests that components of their attentional function might be affected and should be investigated.

The digit-symbol substitution task (DSST) of the Wechsler Adult Intelligence Scale (WAIS) was used to assess attention in patients who had been receiving blocking doses of methadone (80–120 mg) daily for about a year or more. Ex-heroin addicts who had been drug-free for at least 1 year and individuals with no history of narcotic drug dependence served as comparison subjects.

We used the DSST in this study because it has been employed extensively to evaluate the effect of psychotropic drugs (3) and because its performance requires the subject to activate himself, to be alert, and to selectively sequence the execution of simple cognitive and psychomotor activities under the pressure of time. The individual's score is the number of symbols correctly substituted in 90 seconds.

Working (engaged in productive activity) and nonworking groups of methadone patients were tested. Subtle differences in auditory reaction-time (RT) performance between these groups had been found (2), and possible differences in their DSST performance, although of secondary interest, were explored.

METHOD

Data were obtained from 4 groups of 24 subjects: 1) working methadone patients (MW), 2) nonworking methadone patients (MNW), 3) working, drug-free former heroin addicts (DF), and 4) working individuals with no history of narcotic drug dependence (ND). All subjects were men between 25 and 40 years old. The mean ages, in years, were: MW, 31.9±6.1; MNW, 33.0±4.6; DF, 30.1±5.0; and ND, 30.0±5.2. The methadone patients had been receiving blocking doses of methadone daily for 11 months or more at the time of testing (range=11 months to 8 years, mean=2.55 years). Subjects in the DF group had been abstinent from illicit opiates and other drugs of abuse for at least a year.

"Working" was defined as full or part-time employment and/or regular attendance at school, i.e., regular productive activity that was not necessarily gainful. Subjects in the MW, MNW, and DF groups had a minimum addiction history of 2 years. Length of opiate addiction was defined as the cumulative total of periods of daily multiple self-administrations of illicit opiates excluding time spent in jail or prison, in the hospital, in detoxification, in other treatment, or in voluntary abstinence.

We did not test individuals who were receiving a prescribed psychotropic drug or who were likely to have a neurological problem based on self-reports of head or brain injury or of frequent drug overdoses. As part of the screening procedure, each subject was interviewed in detail about drug history, medical history, and waking activities and was given the Cornell Medical Index (4).

The methadone patients came from treatment programs of Beth Israel, Mount Sinai, and other New York City hospitals. The drug-free ex-addicts were obtained from Phoenix House and Horizon Center,

Dr. Appel is Senior Research Scientist and Dr. Gordon is Principal Research Scientist, New York State Office of Drug Abuse Services, Division of Evaluation, 2 World Trade Center, New York, N.Y. 10047.

This work was supported by Alcohol, Drug Abuse, and Mental Health Administration grants DA-00035 and DA-00390 from the National Institute on Drug Abuse to Dr. Gordon and by the New York State Narcotic Addiction Control Commission (now the New York State Office of Drug Abuse Services).

The conclusions expressed herein are those of the authors and do not necessarily reflect the views of the Commission.

which are abstinence-oriented residential drug treatment programs, and were largely high- and middle-echelon paraprofessional staff. The subjects in the ND group were evening college students comparable in background to the patients and nonprofessional staff members of Beth Israel Hospital. Apart from the selection criteria and the age homogeneity of the four groups, subjects were not matched. Information on ethnicity, level of education, and occupational status is reported in detail elsewhere (5).

Task

The digit-symbol substitution task is a paper-and-pencil subtest of the WAIS (6) and is typically used in assessing the performance component of IQ. The DSST has also been used to assess possible functional deficit arising from brain damage or psychotropic drug effects (3).

At the top of the test blank is the digit-symbol code, which consists of a row of 9 boxes. In the upper halves of the boxes are the numbers 1 thru 9, from left to right. In the lower half of each box is a mark or symbol (e.g., a circle, equal sign, inverted T) for each number. The response portion of the test blank consists of 4 rows of 25 boxes, 10 for practice and 90 for actual performance. The numbers are arranged in the upper halves in a somewhat systematic sequence; the lower halves are blank. The subject's task is to fill in the mark or symbol in the lower half that goes with the number in the upper half by consulting the code and to do this for each box consecutively until the 90-second time limit is exhausted.

Design and Procedure

Gordon and Appel (2) found that working and nonworking methadone patients showed differential changes in auditory RT performance across two testing sessions. Thus, we were interested in comparative changes in DSST performance between patient groups. All subjects were given the DSST twice, with approximately a week between the first and second testing. Half of the subjects in each group received the original version of the DSST on their first testing and the other half received an alternate form. On the second testing, the procedure was reversed. The alternate form of the DSST was constructed by selecting a random permutation of the symbols in the digit-symbol code. The numerical sequence of the digits on the response portion of the test blank was not changed.

Testing was done in a quiet room, and the subjects were given standard instructions from the WAIS manual (6). The two testings for a given subject were at approximately the same time of day (within the hour); times of testing varied across subjects. Subjects were paid $5 for each testing session, in which the DSST was the first of several tasks administered.

After each session, a urine specimen was taken from every subject and analyzed for the presence of opiates, methadone, quinine, amphetamines, barbiturates, and cocaine. The technicians who performed the analyses were informed that some of the specimens were from methadone patients. Subjects with inappropriate positives on urinalysis are not included in the results.

RESULTS

The means and standard deviations of the raw DSST scores indicated that the original and alternate forms of the task were equivalent. The largest difference between mean scores on the two tests was 2.4 in the MW group (SDs=10.5 and 7.5 for the original and alternate forms, respectively).

A Groups × Testings analysis of variance was performed to evaluate possible differences between groups and across sessions. There was a significant difference between groups, $F(3, 92)=8.13$, $p<.01$, a consistent increase in scores from test 1 to test 2, $F(1, 92)=105.58$, $p<.001$; and a marginally significant Groups × Testings interaction, $F(3, 92)=2.75$, $p<.05$.

Comparisons between groups were done with Newman-Keuls tests (7). On both testings, there were no significant differences between the MW, DF, and ND groups. The means of each of these groups, however, were significantly higher than that of the MNW group ($p<.05$). When the scores for subjects in the MNW group were converted to T or scaled scores, they were within the normal range according to WAIS norms.

To examine the Groups × Testings interaction further, a one-way analysis of variance was performed with each subject's change score (from test 1 to test 2) as the dependent measure. The results were not significant, $F(3, 92)=1.60$, $p<.10$. The interaction apparently reflects a slightly greater rate of increase in DSST score for the MW and DF groups compared with the ND group. The mean change scores for the MW, DF, and ND groups were 6.2, 6.5, and 3.7, respectively.

Because there was considerable variation in the lengths of maintenance for the patients, the relationship between DSST score and duration of methadone treatment was examined. Correlations between the number of months on methadone maintenance and raw DSST score on the first testing were computed for the working patients, the nonworking patients, and for patient groups combined. The value of r for the MW group was +.375 ($df=22$, $p<.05$); for the MNW group, +.215 ($df=22$, $p>.10$); and for all patients, +.296 ($df=46$, $p>.05$). These results do not provide evidence that cognitive attentional functioning deteriorates with increasing duration of methadone treatment.

DISCUSSION

Our results are consistent with previous data, which, in general, show normal intellectual and psychomotor functioning among methadone patients (2). Although the DSST scores of the nonworking patients were significantly lower than those of the working

patients and the comparison groups, they were within the normal range when converted to scaled scores.

Indefinite maintenance on methadone would be seriously contraindicated if the chemotherapy were associated with deterioration in cognitive capabilities. The three correlations between DSST scores and length of time on maintenance were positive, and two of the three were statistically significant. These results are important because 1) they indicate that with respect to the capacities required for DSST performance the effects of increasing duration of methadone treatment are at least neutral, and 2) as one of the so-called don't hold subtests of the WAIS, the DSST is considered to be sensitive to deteriorative changes (8), which enhances the credibility of the inference of "no decrement." That any of the correlations would be significantly positive was unexpected; however, further comment about this finding is beyond the scope of this study.

The overall DSST results and the correlational data have implications for the rehabilitation of methadone patients. They suggest that adverse effects of chronically administered methadone on cognitive psychomotor functioning are the least likely source of potential difficulties. More likely but often overlooked sources are the civic liabilities and stigmatization associated with the status of "methadone patient." Data presented elsewhere (9) extensively document the administrative, legal, and social barriers and the often capricious personnel policies faced by methadone patients. We are not suggesting that psychopharmacological studies with patients be deemphasized, but rather that there are substantial environmental obstacles to the effective functioning of patients, while the dysfunctional effects of methadone as a chemotherapy are minor.

The finding that the raw DSST scores of the nonworking patients were significantly lower than those of the other groups was unexpected. One possible explanation is that working individuals perform slightly better on the DSST than do nonworking individuals, but this could not be evaluated since unemployed comparison groups were not tested.

Certain characteristics of the lives of many nonworking patients and informal remarks made by several of those tested suggest additional hypotheses. For example, demographic studies (10) have identified a significant minority of the patient population who are acceptably retained in treatment but are unwilling or unable to obtain work or training and who occupy a disproportionate amount of staff time. Such patients appear to have difficulty in mobilizing themselves for virtually any kind of conventional achievement, and the lower DSST scores of the nonworking patients may in part reflect this in a specific performance situation. Given the bleak life situations of many nonworking patients, it is possible that some of these subjects were depressed, and depression and low DSST performance have been reported to be significantly related (11).

Another hypothesis is that some of the MNW subjects were overly aroused or anxious and therefore experienced increased difficulty in the selective control of attention and distractibility (12), which can disrupt DSST performance (13). Despite the experimenter's disclaimers, several nonworking patients expressed apprehension that "poor" performance might in some way jeopardize their employability. Other subjects expressed an equally mistaken but more positive notion, namely, a feeling that if they performed exceptionally well there would be more job opportunities for them. Furthermore, the sheer novelty of participating in the study may have been motivating in itself—several nonworking patients readily acknowledged that the study was "something different" and "something to do." Thus, several important sources of motivation were engaged by the study, and in combination they may have produced overly high levels of arousal for some nonworking patients, with resulting mildly diminished DSST performance.

CONCLUSIONS

There were no indications that the attentional function of methadone patients is adversely affected by high doses of methadone administered in a maintenance schedule. Furthermore, the correlational data indicated that increasing duration of methadone treatment did not adversely affect attentional function.

Portable Electromyograph Monitoring of Unilateral ECT

BY JOHN O. IVES, M.D., LELON A. WEAVER, PH.D., AND RONALD WILLIAMS, PH.D.

The authors describe a portable electromyograph (EMG) designed for use in monitoring unilateral ECT. Administration of muscle relaxants in conjunction with ECT often makes it difficult to determine that an adequate response has been elicited. The authors feel that this adaptation of the EMG provides a useful and easy means of monitoring the presence, bilateralism, and length of the seizure.

ECT IS ONE OF the standard treatments in psychiatry. It involves the application of an electrical current to the head, which induces a typical grand-mal seizure. Because of the musculoskeletal complications of this seizure it is now standard practice to administer ECT after the patient has received barbiturate anesthesia and muscle relaxants such as succinylcholine. A further refinement of the technique has been to apply the electrical current unilaterally to the nondominant hemisphere, thereby reducing the transient memory dysfunction that often follows ECT (1–3).

These refinements in technique occasionally cause certain complications in the administration of ECT. It is generally accepted that a bilateral tonic-clonic seizure must take place if maximum treatment benefit is to be obtained (2–4). However, the use of muscle relaxants often makes it difficult to determine that an adequate response has been elicited. It is particularly difficult to determine that the seizure is bilateral, since movements of the trunk can produce passive movements of the limbs that are similar to movements due to muscle contractions.

The authors are with the University of Vermont, Burlington, Vt. 05401, where Drs. Ives and Weaver are Assistant Professors, Department of Psychiatry, College of Medicine, and Dr. Williams is Associate Professor, Department of Electrical Engineering.

METHOD

In order to overcome these difficulties, a portable electromyograph (EMG) was developed that can be easily applied to the patient's calf muscle just prior to treatment. It consists of a differential follower input stage, a high-gain difference amplifier circuit, a filtering section, and an output power amplifier driving an audio speaker. The EMG is battery operated to avoid accidental ground loops from other electrical equipment.[1] It measures 10.2 cm by 15.2 cm by 20.3 cm and thus is small enough to be placed on the bed next to the patient. It takes less than a minute to apply.

When the apparatus is connected to a normal, resting muscle it emits a sound of moderate intensity. When the succinylcholine begins to depolarize the muscle an intensification of this sound occurs, at which time muscle fasciculation is often clinically apparent. After a few seconds this fasciculation stops and the apparatus becomes silent, indicating that the muscles are relaxed and the patient is ready for the treatment. When the treatment is applied a short burst of sound indicates passage of the stimulating current; this is followed by a short latent period and then a sustained loud sound that indicates the tonic phase of the seizure. This sound can be heard even though the patient's muscular activity may not be readily apparent. After the tonic phase of approximately 10 seconds, the clonic phase occurs, characterized by intermittent bursts of sound and followed by a silence at the end of the seizure. Since the current is applied to one side of the head and the apparatus is applied to the ipsilateral leg, proof is obtained that the seizure is indeed bilateral. The tonic and clonic phases can also be easily timed by listening to the apparatus.

[1]Details of the electromyograph's construction are available from the authors on request.

DISCUSSION

A number of the methods of monitoring the progress and use of ECT have been reported in the literature. The most widely known method is that of Blachly and Gowing (5) who followed the course of multiple ECT with EEG and EKG monitoring. They reported that EEG evidence of convulsive activity persisted long after muscular evidence of a seizure stopped. Since EEG monitoring is crucial in multiple ECT, it follows that EMG monitoring alone is not sufficient for this purpose. However, while EKG and EEG monitoring is required for multiple ECT, it is usually not necessary in cases where a single session of ECT is given, except in those cases where cardiac complications are present.

Holmberg (6) discussed the use of an EMG to monitor the length and intensity of the convulsions produced by a standard ECT stimulator used in conjunction with the administration of oxygen. Inman and associates (7) used the EMG in a relatively similar way. In both of these cases the EMG was large and cumbersome, and while it would be useful for research purposes it would not be so useful for clinical purposes. Since our apparatus is small and easily applied, it is more readily adapted to clinical use. Articles in both the scientific literature (8) and in the lay press (9) have documented the occasional unreliability of ECT instruments. Because of this problem an external monitoring source that documents the presence, bilateralism, and length of the seizure is of clinical relevance.

We therefore feel that this adaptation of the EMG is a useful means of monitoring unilateral ECT modified with muscle relaxants.

IN MEMORIAM

George Herbert Stevenson 1894–1976

DR. GEORGE H. STEVENSON, a former President (1940–41) of the American Psychiatric Association and one of the founders of the Canadian Psychiatric Association, died in Florida on June 1. With his death the psychiatric community lost a scholar and a humanitarian who devoted his professional life to mental hospital administration and preventive psychiatry.

Born in Toronto, he moved with his family to Hamilton, where he completed high school. His heart was already set on a medical career, but since he was only 16 and needed money to finance his medical studies he worked for 2 years in a variety of jobs. He entered the medical school at the University of Toronto in 1912. His medical education was interrupted by World War I: he enlisted in the Canadian army in 1915. He spent the next year as a medical attendant in a military hospital in Salonika. Urged by the authorities to complete his medical education, he returned to Canada and graduated in 1918. He was then posted to the medical staff of a military mental hospital in Newmarket, Ontario. After the war he joined the Ontario Provincial Mental Hospital Service. Given leave for postgraduate study, he studied briefly at Harvard in 1920, and in 1927, with the help of a Rockefeller Fellowship, he worked in Boston and Baltimore. On his return he became Medical Superintendent of the Ontario Hospital at Whitby, where he remained for 7 years. Interested in the psychiatric role of the nurse, he developed a graduate course for nurses in psychiatry—the first in Canada.

In 1934 Dr. Stevenson moved to London as Superintendant of the Ontario Hospital and Professor at the University of Western Ontario. During the next 18 years he developed an international reputation as a psychiatric specialist. He became president of the London Academy of Medicine, the county medical society, and the London Canadian Club. He was a fellow of the Royal Society of Canada and served on the executive boards of numerous other associations.

He held many positions in the American Psychiatric Association, including being a member and then chairman of the Committee on Nursing and the Public Education Committee. After serving as APA President in 1940–41, he organized and chaired the Committee on International Relationships. For 7 years he represented the APA on the American Board of Psychiatry and Neurology and was an ex-officio member of the APA Council (Board of Trustees) until his death.

In Canada he chaired an interim committee that worked for several years toward the organization of a national psychiatric association. He chaired the inaugural meeting of the Canadian Association in Montreal on June 20, 1951.

Taking an early retirement from the Ontario Hospital Service in 1952, he directed a major study on drug addiction for the province of British Columbia. In 1956 he moved to Hawaii to begin a second career as a community psychiatrist and a consultant to both the state hospital and the School of Social Work at the University of Hawaii. In 1969 he returned to Canada, but after suffering a stroke in 1970 he entered a nursing home in Florida, where he remained until his death.

The major thrust of Dr. Stevenson's professional career was mental hospital administration. His experience in Canada made him sensitive about political interference in this field. Years before such ideas were common he urged that mental hospitals be administered by local boards of management. He strongly advocated the development of community psychiatric clinics and psychiatric units in general hospitals.

His therapeutic approach was eclectic. He was irritated by the cultism he perceived in the competing schools of psychotherapy, believing that one type was pretty much as effective as another. However, he was interested in innovative forms of treatment and prevention. One of his major contributions was the use of maintenance ECT to prevent recurring manic-depressive attacks long before the introduction of lithium.

In his teaching, Dr. Stevenson constantly emphasized the necessity of respecting the dignity of the patient. He insisted that patients be addressed by their proper names and never tolerated the use of derogatory terms such as "lunatic" or "crazy" in his presence. He rejected the auditorium lecture-demonstration as a method of teaching medical students and instead used small bedside teaching clinics. He was committed to the integration of psychiatry with general medicine and the behavioral sciences.

His presidential address was delivered as the United States was entering World War II. In it he stressed his conviction that war was a major psychiatric public health disaster. He felt very strongly that psychiatrists could do much more than they had in the past to prevent war. Only toward the end of his career did he reluctantly come to the conclusion that probably psychiatrists would be better advised to stick to what they knew and did best—treating mentally sick patients and trying to prevent mental illness.

The last time I talked with Dr. Stevenson was in Florida several months before his death. Our conversation reminded me of something he had written some years before:

> As there is so little time and so little opportunity in our tense high pressure world for dreams and for relaxation, I commend the armchair to my readers. . . . In such an armchair your old men might dream dreams and your young men might see visions. (1, p. 82)

LETTERS TO THE EDITOR

Craft Versus Profession in Alcoholism Treatment

SIR: In "The Future of Alcohology: Craft or Science?" (June 1976 issue), Melvyn Kalb, Ph.D., and Morton S. Propper, M.S.W., suggested an inherent conflict between the professional-scientific perspective on alcoholism and the craft-like role of the nonprofessional therapist. In actuality, difficulty in achieving active collaboration between the two groups results much more often from power politics than from genuine incompatibility. For example, in the university-based alcoholism program that I direct, where final control resides in a multidisciplinary, eclectic faculty, patients may attend Alcoholics Anonymous (AA) meetings in the clinic while also participating in traditional psychotherapeutic counseling or pharmacotherapy. Our counselors, many of whom are active AA members, are flexible about the issue of abstinence, and patients are involved in an active self-help therapeutic program with strategic intervention from professional staff.

Professionals have much to gain by adapting techniques from the nonprofessional self-help groups, which clearly have effective therapeutic measures at their disposal. After a careful review of studies on AA, Baekeland and associates (1) concluded that the organization produces an overall improvement rate comparable to that of professionally directed programs. Future studies may help define the actual vehicles of improvement in self-help settings so that these approaches may then be applied in clinics. For example, we examined the marked decline in alcohol and drug use in a charismatic religious sect and ascertained by multiple regression analysis that specific facets of social cohesiveness and meditation practice were "treatment" variables that best predicted positive outcome (2).

Given the increasing demand for alcoholism services, it seems important for professionals to develop new means for utilizing nonprofessional self-help techniques, rather than defining conflicts between the two groups as insoluble.

MARC GALANTER, M.D.
Bronx, N.Y.

SIR: The article by Dr. Kalb and Mr. Propper brings important issues to the surface and accurately defines many aspects of the relationship between some paraprofessional counselors and some mental health professionals in the field of alcoholism treatment. The brush, however, sweeps too broad in treating the two fields as unified, opposing bodies. In addition to the conflicts between professionals and counselors, each group faces considerable diversity of emphasis and orientation within itself.

The authors conclude that alcohology will have to choose between counselor or professional lines because the two models cannot coexist. That is not my experience. The key to their coexistence is the proper assignment of roles. The professional should define the patient's problems and prescribe the overall treatment approach. When patients are properly assigned to counselors, many will be helped. It is not necessary to ask either the counselor or professional to lose face or faith. Just as the architect and the carpenter both have roles in the building of a house, the professional and the counselor both can have roles in the reconstruction of the life of the alcoholic.

ROGER PEELE, M.D.
Washington, D.C.

SIR: Dr. Kalb and Mr. Propper state that combining a craft approach and a scientific line "prevents growth and progress." This has not been my experience at the Oregon Alcohol Treatment and Training Center over a 10-year period. Among the helpful adjuncts in our program is the requirement that professionals and paraprofessionals attend weekly journal clubs, in which clinical material from *all* sources is presented and discussed, and staff meetings wherein clinical decisions are made concerning patients. This is a maturing process. At times, a paraprofessional might be more in favor of using disulfiram or other medication than the professional.

I would also point out that "folk science" is not practiced solely by the craft group. I have chosen the following from many possible examples. An alcoholic patient remarked that in his two years in psychoanalysis the analyst felt that if the patient stopped drinking, the true nature of his problems could not be analyzed. Today, this patient is on disulfiram, is making good progress in therapy and has stated, "Psychoanalysis would never have worked for me."

EDWARD M. SCOTT, PH.D.
Portland, Ore.

Dr. Kalb and Mr. Propper Reply

SIR: Drs. Scott and Galanter cite their own alcoholism programs as examples of settings in which active collaboration between professionals and paraprofessionals exists without the strains referred to in our article. However, both of these programs are examples of professionally oriented clinics. Drs. Scott and Galanter are nationally recognized authorities who undoubtedly exercise considerable discretion in the selection and training of their staffs. These programs can hard-

ly be taken as representative of the vast majority of alcoholism treatment clinics in this country.

Also, as we noted in our article, the issue is not the relative effectiveness of professionals and paraprofessionals in the treatment of alcoholism. Our intention was to explore the problems inherent in the integration of the results of empirical research within a craft-oriented treatment structure and to consider the implications of these problems for the present and future of the alcoholism treatment effort as a scientifically based enterprise.

Dr. Peele stresses the differential roles and responsibilities of the professional and paraprofessional as "the key to their coexistence." He asserts that "The professional should define the patient's problems and prescribe the overall treatment approach." To the extent that such a situation obtains, we would agree that compatability is possible and desirable. However, it is precisely the *lack* of such clear role differentiation that characterizes most treatment settings and engenders the problems we have addressed.

We quite agree with Dr. Galanter that the field is hampered by "power politics" rather than being an open marketplace of ideas. Pattison has said,

> the field of [alcoholism] treatment is dominated by paraprofessional values, attitudes, and concepts. This is now leading to an ideological conflict between the established paraprofessional approach to treatment and new scientific approaches to treatment. (1)

The recent diatribes in the public media against the authors of the Rand Corporation study "Alcoholism and Treatment" (2) demonstrate what a "maverick" professional must be prepared to encounter. The report was described as a "cruel hoax" by representatives of the National Council on Alcoholism, who acknowledged that they had not even seen it before making their denunciation (3, 4).

Our article addressed the issue of ethics and responsibility in the treatment of those who choose to seek help from a nominally professional establishment. We do not doubt that some paraprofessional counselors have much to offer or that the integration of professional and paraprofessional efforts is much to be desired. However, the historic inertia of clinical alcohology in the face of empirical research findings forces us to a consideration of the immediate and long-term effects of the current marriage of craft and scientific perspectives.

We note that Drs. Scott, Galanter, and Peele do not question those assertions in our article which are of central import, for example, our statement that "Research is not used, as in other fields, as a springboard for developing and testing new hypotheses and abandoning old ones that are empirically disproved." In a vividly illuminating work, Rossi and Filstead (5) addressed many of the same issues.

Problems in integrating research findings into the mainstream of clinical practice exist, as Drs. Scott, Galanter, and Peele tacitly acknowledge. If our article serves to bring these problems into sharper focus and to stimulate dialogue, we will have accomplished our goals.

A Therapeutic Example

SIR: The article by Bernard L. Greene, M.D., and associates on "Marital Therapy When One Spouse Has a Primary Affective Disorder" (July 1976 issue) describes a problem often encountered in the practice of child and family therapy, namely, the parent-spouse in a PAD crisis creating family disequilibrium that may be manifested in symptoms in a child and/or in marital problems. The nonafflicted spouse must bear a major burden in the restoration of family equilibrium during these episodes. Strong support from the therapist is essential in interrupting the interpersonal cycle that frequently occurs in these situations. The non-PAD spouse is simultaneously induced into and rejected from the role of nurse or therapist by the PAD-afflicted spouse, who withdraws and declares him/herself dysfunctional. Neither retains the capacity or authority for the regulation of distance or involvement, and both threaten either suicide or leaving the home. At this point, the therapist as legitimate authority is needed to "prescribe" proper regulation of distance and involvement.

In one such case I recently saw the non-PAD wife, who initially presented herself as a persistent "nag." She was told that she was permitted *not* to function as a hovering nurse, and the therapist took the responsibility for a possible worsening of her husband's depression if she did this. Her husband went from being furious at her for "nagging" to being furious at the possibility of abandonment, but when she was helped to remain in this new position, he became activated to increase his participation in the family and return to work. His wife learned that she had the right to move herself out of an impossible situation and that this move did not cause a disaster in her family.

Consistent with the idea that stimulation of healthy resources is a primary function of the therapist, the support of the nonafflicted spouse in families with PAD should be a major component of the treatment program. Although structuring of distance and involvement does not provide the total solution, it has distinct value in periods of crisis when there is no hope of movement from a cycle in which mutual distress can only escalate.

RICHARD C. EVANS, M.D.
Tarrytown, N.Y.

Etiology and Differential Diagnosis of the Morbid Jealousies

SIR: In "A New Concept and Finding in Morbid Jealousy" (June 1976 issue), John P. Docherty, M.D., and Jean Ellis, R.N., reported three cases in which a pathologically jealous male had observed his mother engaging in sexual infidelity. The authors suggested that this finding is of major etiologic

significance. However, they did not comment on another factor they also reported, i.e., the presence of alcohol abuse in at least two of the three cases.

Although morbid jealousy apparently can occur in many settings, alcohol abuse is a well-known factor in many cases (1–3). Excessive alcohol consumption impairs higher cognitive function in general (judgment, discrimination, reasoning, etc.), decreases impulse control, increases aggressiveness, and can exacerbate paranoid personality tendencies to delusional proportions (3, 4). Alcohol abuse can also interfere with normal male sexual function, thereby heightening anxiety and undermining sexual identity (5, 6). All of these effects can contribute significantly to the paranoid clinical picture described by Dr. Docherty and Ms. Ellis, and alcohol abuse should not be omitted in discussing the etiology or planning the treatment of such cases.

C. GIBSON DUNN, M.D.
Richmond, Va.

Dr. Docherty Replies

SIR: We appreciate Dr. Dunn's careful reading of our article. His comment raises the interesting issue of the differential diagnosis of the morbid jealousies, which we examined only briefly in our paper due to space considerations. We indicated, however, that on the basis of our own observations and literature review we recommend dividing the morbid jealousies into three categories: excessive, obsessive-delusional, and ego-dysfunctional.

The term "excessive jealousy" is used to describe those patients who respond with an extreme reaction to situations generally recognized as jealousy provoking. "Obsessive-delusional jealousy" delineates a group of patients with no other manifest disturbance of ego function who are continually preoccupied with the suspicion or belief that their spouses are sexually unfaithful. "Ego-dysfunctional jealousy" describes patients who experience delusions of infidelity in the context of some serious disturbance of ego functioning, such as schizophrenia, toxic states, or dementiform conditions.

Although alcohol consumption did exacerbate the symptoms in our patients—primarily in the form of decreased impulse control—and was considered as part of the overall treatment, it did not seem central to the presence of pathological jealousy in these men. As we mentioned, they all had the obsessive-delusional form of this disorder, and persistent concern with thoughts of their wives' infidelity preceded their excessive use of alcohol. Moreover, these concerns were present whether or not the patients were drinking. Clinically, what is important is that these men were more likely to act on their suspicions if they were drinking. Thus, it would seem that alcohol was more of an amplifying than an etiologic agent for these patients. Indeed, with regard to the somewhat dubious entity called "alcoholic paranoia," Dr. Chafetz states in the text cited by Dr. Dunn that "This category represents another attempt to emphasize the alcoholic complication instead of the larger underlying problem."

There does, however, seem to be a group of patients for whom alcohol can be a more direct determinant of the appearance of pathological jealousy. In one careful study of the relationship between alcoholism and morbid jealousy, Kolle (1) isolated a group of patients who experienced convictions of infidelities by their spouses primarily in association with acute intoxications. We would categorize these patients as suffering from ego-dysfunctional jealousy, toxic subtype. In these patients, jealous attacks seem dependent on the disturbances of higher cognitive functions that Dr. Dunn describes as secondary to intoxication. This condition, however, is probably rather rare. Shepherd (2) found only 1 such case in his review of 81 unselected cases of morbid jealousy.

Finally, even if we accept the fact that conditions such as dementia, schizophrenia, and toxic states produce a disturbance of ego functions that facilitates the appearance of morbid jealousy and delusions of infidelity, we are still left with the question of why that particular content appears. The life histories and psychodynamics revealed in the cases we studied suggested, we feel, a possible answer to this question for at least one form of the disorder.

New Haven, Conn.

Is Psychiatry Doing the Job?

SIR: I would like to take issue with the following statement by Bertram S. Brown, M.D., in "The Life of Psychiatry" (May 1976 issue): "My answer to the question of whether psychiatry is up to the task of dealing with serious mental illness and whether it is doing the job has to be yes." To individuals in situations like mine—working directly on a ward for multiple recidivists in a so-called intensive short-term psychiatric institute—the answer cannot be yes. There is too much recidivism and other evidence of unsatisfactory results. Of course, some relapses will occur as patients gradually adjust to the community, but our committee studying the recidivistic patient found that most such patients are no better off after the 4th or 5th or 10th relapse than before they originally came to this or other such hospitals.

The current approach, directed at crisis resolution or used as an expedient, does not even attempt to be definitive for the illness. The hope that the community would serve to re-

habilitate the seriously ill after a brief hospitalization has not generally been realized and perhaps cannot be until we rethink the subject of psychiatric rehabilitation and reconsider how best to prepare our patients for the pressures involved. For patients who are not seriously ill and can learn from a transient breakdown, Dr. Brown's "yes" answer makes sense.

IRVING M. ROSEN, M.D.
Cleveland, Ohio

Dr. Brown Replies

SIR: Dr. Rosen's letter on the need to rethink the subject of psychiatric rehabilitation raises an issue of great concern to me, both as a psychiatrist and as an administrator.

In the amelioration and control of symptoms of mental illness, progress in psychiatry has been dramatic. These advances make it possible for me to believe that psychiatry *is* up to dealing with serious mental illness and that, to a large extent, it is doing the job. On a psychopharmacologic basis, psychiatrists are able to provide much more effective help to people suffering from depression or psychoses than we were 25 years ago. Perhaps when we can solve such problems as compliance and adverse side effects, our progress will extend even further.

Clearly, however, medical treatment of the illness alone is not sufficient. People subject to severe and repetitive mental disorders usually require multiple supportive and rehabilitative services, many of which have traditionally been defined as outside the scope of psychiatry per se. If psychiatric rehabilitation is to be fully effective, a range of services must be continuously available on a long-term basis. To reach the people most in need of help, services must be relevant to their everyday problems in living and must be aggressively promoted. Even under the best of circumstances, relapses can be expected and occasional episodes of intensive treatment will be required. Nonetheless, much can now be done to minimize the negative consequences of the illness or disability for the patient, the family, and the community.

As an administrator looking at nationwide services for persons with chronically disabling mental health problems, I believe it is increasingly clear that in addition to effective psychiatric input and new technologies, future progress will depend in large part on improved administrative and fiscal mechanisms to promote development of comprehensive psychosocial rehabilitation services on a broader scale. The gap between current knowledge and actual practice is immense. Despite many well-documented research and demonstration projects in psychiatric rehabilitation, thousands of people are not currently receiving optimal help.

I am encouraged that these problems are now being looked at carefully—by professionals, by congressional committees, by the National Institute of Mental Health, by consumer groups, by hospital employees, and others. Perhaps in the next few years we will be able to identify and remove some of the administrative and political barriers contributing to the present dilemmas and contradictions in community care. Psychiatrists can and should provide leadership in this process, at the same time recognizing that our profession alone cannot accomplish all that needs to be done, either clinically or administratively.

BERTRAM S. BROWN, M.D.
Rockville, Md.

Death Fantasies as an Escape Mechanism

SIR: "Is Dying Being Worked to Death" by Ronald Jay Cohen, Ph.D. (May 1976 issue) brings up important considerations related to clinical psychotherapy as well as to everyday philosophy. Dr. Cohen is justifiably concerned that outpourings of articles and books on death and dying, described by some as a "bandwagon" phenomenon, are matters of serious interest to many, including neurotic patients.

The papers Dr. Cohen refers to were chiefly written during the past 3–5 years, but Dr. Paul Schilder and I studied this subject as long ago as 1933. At that time, we were interested in the attitude of normal and neurotic individuals concerning the clinical manifestations of the "death instinct." We administered a questionnaire to a large number of staff and students at the Bellevue Psychiatric Hospital, New York University, and elsewhere (1). Our analysis indicated that apparently normal people were preoccupied with thoughts of death and dying when the need arose to escape from various unbearable situations in life; this served as a sort of sublimation mechanism. For example, death thoughts meant final narcissistic perfection, gratified masochistic tendencies, forced affection where it was withheld, etc. Our final epigram covered the conscious and unconscious meaning of death fantasies, to wit: "All libidinous roads lead to death and death thus becomes the perfect symbol of life."

In a subsequent paper (2), we used the same questionnaire method with neurotics and schizophrenics to examine the importance of separation anxiety from love objects in death obsessions and fantasies of these patients. In effect, the findings were the same as those in normal subjects except that a greater degree of unconscious fear of loss of incest-objects was observed among severe neurotics and psychotics.

Agreeing with the existentialist Heidigger, who wrote of "the existence towards death as a continuous human experience," our main conclusion was that consciously and unconsciously human beings strive toward life and not toward death. Clinically, we found little evidence of the *Trieb* toward extinction.

As to the reason for the recent "heightened interest in death-related phenomena" about which Dr. Cohen and others speculate, could it be that today's increased longevity accounts for and stirs up our interest in death? Actually, however, there is no reawakening of preoccupation with death and dying, only a broad exposure among the laity in these days of psychological sophistication and expanded self-awareness.

WALTER BROMBERG, M.D.
Sacramento, Calif.

Dr. Cohen Replies

SIR: I would like to thank Dr. Bromberg for calling attention to his prior work and contributing his thoughts on my paper. The heightened interest in death-related phenomena

manifest in current books, essays, and specialized professional journals (e.g., *Omega: The Journal of Death and Dying, Archives of the Foundation of Thanatology*) may indeed be related to increased longevity, as Dr. Bromberg suggests. However, "allowing for discussion of ethical and legal issues raised by medical advances," consideration of the many multifaceted explanations for the subject's increased general popularity remains academically intriguing. In an applied context (with reference to the work of Drs. Bromberg and Schilder) I would agree that psychotherapists must remain attuned to the psychodynamic and behavioral consequences that a death-related preoccupation might hold for an individual patient. To underplay the importance of a fellow's existential struggle would surely be a grave error.

RONALD JAY COHEN, PH.D.
New York, N.Y.

Lithium—Depressant or Antidepressant?

SIR: In his letter "Lithium and Depression" (August 1976 issue) Robert O. Friedel, M.D., noted that lithium can exert either a depressant or an antidepressant effect, depending upon its dose. This is one aspect of a phenomenon I have observed frequently over the last few years that has important therapeutic implications. Lithium has a U-shaped dose-response curve, possibly even an undulating one. For many depressed patients, at the lowest dose lithium exerts a depressant effect, at a somewhat higher dose an antidepressant effect, and at an even higher dose a depressant effect again. Unlike Dr. Friedel I have not found that any specific serum lithium level determines points of reversal of effect.

What is even more important is that the phenomenon is characteristic not only of lithium but also of phenothiazine and thioxanthine tranquilizers. I have worked primarily with thiothixene (Navane) but also have used chlorprothixene (Taractan) and chlorpromazine (Thorazine), and I suspect that these observations pertain to all of the tranquilizing medications in these groups. There is a dose in the range of 0.5–5 mg at which thiothixene exerts an antidepressant effect; below and above this dose, it has a depressant effect. Among patients who become depressed only and show no hypomanic or manic episodes, this dose is relatively low. Among those patients who occasionally display hypomanic or manic episodes, the antidepressant dose is somewhat higher and the range of the antidepressant effect is broader. It is my experience that lithium does nothing that these other tranquilizers will not do if used in these relatively small doses.

This effect can be used therapeutically. I have found that between one-half and two-thirds of depressed patients will experience relief from depression within 24 hours, with minimal danger of toxicity or side effects, once the correct dose of tranquilizer is found. If the small dose of tranquilizer is superimposed on a subthreshold dose of an antidepressant agent or an adequate dose before it has had time to take effect, the response will be much more striking.

If my observation is correct, it implies that lithium does not have the specific relation to manic-depressive illness that is commonly attributed to it. It seems to have this relation because it is so toxic that it can be given only in small doses. Phenothiazines and thioxanthines are far less toxic and are therefore given in relatively larger doses that can exert a therapeutic effect on schizophrenic episodes but are too large to display the antidepressant effect that I have mentioned.

Interested readers can find more extended discussions of this technique of treatment in two previous publications (1, 2).

Fatal Aspiration

SIR: There is not sufficient evidence in the case reported by Robert F. Bort, M.D., in "Catatonia, Gastric Hyperacidity, and Fatal Aspiration: A Preventable Syndrome" (April 1976 issue) to support his hypothesis that the aspiration is in some way related to the patient's underlying schizophrenic process and esophageal dysfunction. We are not told anything about the patient's physical or neurological status, how he was fed, his eating habits (did he "wolf down" his food or chew it?), and his overall pharmacological and other treatment (was he restrained?). These are all factors that might have been involved in the patient's episode of aspiration.

I do not believe that aspiration is necessarily part of a subtle neurophysiological dysfunction in schizophrenia. This may be true for some patients, but others may aspirate on the basis of drug-induced mechanisms. Plachta (1) has reviewed the evidence that atropine-like drugs may lead to loss of control of esophageal sphincters as well as depressing respiratory ciliary activity. I have hypothesized (2) that phenothiazines may cause a bulbar palsy-like syndrome (with possible aspiration) similar to that described by Malitz and associates (3).

It is obvious that further work is necessary to elucidate the causes of fatal aspiration in drug-treated schizophrenics as well as the so-called café coronary and seizures. My own hunch is that there are many causes and, unfortunately, the state of the art and science of treating schizophrenia will not prevent any of them.

KENNETH SOLOMON, M.D.
Albany, N.Y.

Dr. Bort Replies

SIR: Although I would not deny that phenothiazines may play some as yet unspecified role in aspiration deaths in schizophrenic patients, there are adequate studies indicating

that approximately 50% of *untreated* schizophrenic patients have cineradiographic abnormalities of esophageal function (cricopharyngeal dysfunction and pooling of contrast material within the valleculae and pyriform sinus region). Administration of chlorpromazine had no effect on these abnormalities (1, 2). The effect of phenothiazine drugs on the respiratory ciliary activity is certainly better established, although of unknown clinical importance.

However, I think that Dr. Solomon may have overlooked the major point that I wished to make: regardless of etiology, it is not the aspiration that kills these patients, be they acutely ill schizophrenics or women in labor, but the pH of the gastric aspirate (3). Thus, I offered the recommendation for antacid medication as a preventive measure.

Concerning the specific questions raised about the patient I reported on, I offer the following information. Physical and neurological status remained within normal limits up to the agonal event except as noted in the case report. A mechanically soft diet was prescribed and hand feeding was frequently required. There was no known feeding four or five hours prior to death. The patient was not secluded or restrained during the week before his death; he preferred to lie on a mattress placed on the floor of a large room.

I would like to emphasize that this patient was not asphyxiated by a bolus of food as in the "café coronary syndrome."

Ann Arbor, Mich.

Polarization or Specialization?

SIR: The terms "biological" psychiatrists as opposed to "dynamically oriented" or "analytically oriented" have been appearing regularly in the *Journal*. Dr. Bertram Brown's recent overview article (April 1976 issue) and Dr. Joel Kotin's letter (July 1976 issue) use these polarities.

Capable and flexible clinicians I know simply do not fit such typologies; such clinicians are comfortable with various theories of illness and the spectra of therapies. As the world grows more crowded and tense, polarization in many areas increases. Political, economic, and social extremes come into greater focus; it is perhaps in that context that psychiatry may be seduced into dividing itself up where insufficient basis for division exists in reality.

AVRUM EDWARD PASTOR, M.D.
Burlingame, Calif.

More Violent Capgras

SIR: I would like to describe my experience treating a case of Capgras syndrome in a 27-year-old married man with three children. The primary diagnosis in this patient is schizophreniform psychosis with paranoid features. He is convinced that his parents and children are strangers who are being paid by an unnamed foreign power and are trying to spy on him. His conversations with me of late have shown an increased desire to become violent toward these supposed impostors. He has made several elaborate plans to torture his parents and children in order to find out the "truth." Robert Weinstock, M.D., previously reported a case of Capgras syndrome that actually led to violence (letter to the editor, July 1976 issue).

Treatment with fluphenazine decanoate and oral fluphenazine in combination have lessened my patient's previously strong impulses to harm his parents and children, although he still thinks about it occasionally. However, the delusion about the identity of his family still remains.

D.L. CRANE, M.D.
New York, N.Y.

Virilizing Influences, Sexual Behavior, and IQ

SIR: Jerome D. Goodman, M.D., has collected very interesting data which he presents to good effect in "The Behavior of Hypersexual Delinquent Girls" (June 1976 issue) to support the hypothesis that there are important biological determinants of behavior.

There are two points, however, with which I take issue. The first of these, tangential to Dr. Goodman's work, is the unfortunate and perhaps unintended implication that contraceptive availability contributes to "problem sexual behavior." In fact, there is evidence suggesting that a pattern of regular sexual intercourse is usually established *before* a teenager takes action to obtain contraception (1, 2). It appears that many young women in today's culture are prepared to risk pregnancy rather than abstain from coitus.

The second point relates to the hypothesized above-average intelligence of girls exposed to virilizing influences during or before childhood. It would be interesting to know the IQs and socioeconomic status of the parents of the girls in Dr. Goodman's sample; it is possible that their intelligence could be explained by these factors alone. For example, after publication of the Ehrhardt and Money (3) study cited by Dr. Goodman, it was discovered that, although daughters born to progestin-treated mothers had higher IQs than did control subjects, their IQs were *not* elevated in comparison to their own sisters who had not been androgenized in utero.

3. Ehrhardt AA, Money J: Progestin-induced hermaphroditism: IQ and psychosexual identity in a study of ten girls. Journal of Sex Research 3:83–100, 1967

VIRGINIA ABERNETHY, PH.D.
Nashville, Tenn.

Dr. Goodman Replies

SIR: In reply to Dr. Abernethy's comments, I am aware that contraceptive measures do not necessarily engender problem sexual behavior in a direct causal relationship. On the other hand, availability of contraceptive devices, information, and supportive understanding of early sexual experi-

ence can be thought of as tantamount to subtle sanction—as though "praising with faint damns."

It is my contention that "problem sexual behavior" refers to the problem of parents who are often at a loss to comprehend the increasingly early arrival of sexual attitudes and experiences of their children. Thus early sexuality may be a product of biological change, and such change may be more relative to earlier menarche and—as is my thesis—biological priming. It has been my experience that parents were relieved to learn that the sexual drivenness of their daughters was possibly related to biology rather than the cliché of sexual acting-out of unconscious factors.

Dr. Abernethy's point regarding the relationship of above-average intelligence and exposure to virilizing influences illustrates the need for further study in this area. Intelligence is the summation of multifactorial input, and it could as easily be stated that the sisters of daughters born to progestin-treated mothers grew up in enhanced environments, with the primary progestin-enhanced sibling serving as additional input. It may be very difficult to reach endpoints of determination in this area, because it remains unsettled as to whether intelligence can ever be conceived of as an absolute or relative capacity. In the small number of cases that I described, I have no data about the IQ of parents, but my impression of their socioeconomic status was that the assembled cases were representative of the general population.

I am convinced that there are other girls who have been primed with virilizing agents whose sexual behavior represents only part of a cluster of symptoms. It remains for practitioners to keep the possibility in mind, ask for the relevant history, and assemble data. Then the matter of whether enhanced intelligence as a result of virilizing agents is a valid concept can be approached through matched studies using control samples.

JEROME D. GOODMAN, M.D.
Saddle River, N.J.

Natural Selection and Neurosis

SIR: In his thoughtful attempt at explaining the relationship between the high prevalence of neurosis and Darwinian theory in "The Role of Neurosis in Phylogenetic Adaptation, with Particular Reference to Early Man," Leon Sloman, M.R.C.S., L.R.C.P., erred in certain important ways.

First, the term "neurosis" is used incorrectly. To gloss over the distinction between neurosis and psychosis is a repudiation of our efforts to understand the origins and manifestations of psychopathological syndromes. We are beginning to discover differences in how psychiatric illnesses are genetically transmitted, and this information is certainly relevant to a paper on evolution. If Dr. Sloman does not feel this is the case, he should have offered more reason for excluding this vital area. Furthermore, Dr. Sloman purposely omits from his definition of neurosis "the adaptive reactions of personality to anxiety and depression." I believe this omission is untenable. The cognitive, emotional, and behavioral reactions to painful affect, whether such reactions seem adaptive or not, form an essential component of neurosis.

Second, in applying the concept of natural selection to the human condition, there is always the danger that the observer will defend what seems to him to be successful and condemn as less fit that which he happens to dislike. According to Dr. Sloman, neurosis was more likely to occur in persons with poorer genetic endowment than the group at large. These unfortunate prehistoric neurotics presumably felt inferior and became anxious and depressed because they really were inferior. Eventually, in his view, their less adequate genetic contribution to the species was lost, and the genetic complement of the species was benefited. The position that is implicitly defended by this incorrect application of evolutionary biology is that one who is emotionally healthy is likely to be genetically superior to his depressed or anxious neighbor.

Third, the fact that we possess a potential to be neurotic does not mean that our becoming so is determined, to any degree, by our genes. Neither does it follow that because we suffer from neurosis, neurosis fulfills a purpose, even the grand purpose of enhancing phylogenetic adaptation.

Our genetic endowment is a broad avenue, not a side street. It allows for much choice and freedom. I believe it is cynical in the absence of scientific evidence to speculate that we are determined more than the facts suggest.

DOUGLAS H. INGRAM, M.D.
New York, N.Y.

Dr. Sloman Replies

SIR: My operational definition of neurosis was restricted for heuristic purposes. I prefer to use the term "neurosis" because the other theories I refer to use it and appear to have addressed themselves to the same phenomenon I have. Introduction of another term would have confounded the issue.

I agree with Dr. Ingram about the importance of differentiating the genetic mechanisms of neurosis and psychosis. I refrained from doing so, initially, only to avoid a dilution of focus. I believe that there is convincing evidence of a direct genetic transmission of psychosis (1), and that the predisposition to neurosis is present in all of us but the emergence of neurosis is the result of an interactional process. There is no evidence of any specific gene or group of genes directly contributing to susceptibility to neurosis.

Dr. Ingram's basic objection seems to be his perception of an implied link between neurosis and genetic inferiority. I emphasized that my hypothesis applies to prehistoric man. In our society, the "Peter principle," which states that one rises to one's highest point of inadequacy, makes it harder to relax and enjoy one's successes (2). For this reason and because of technological and medical progress, Darwinian natural selection can be said to no longer apply in our society (3).

Although my hypothesis does not apply to contemporary society, it is possible that those who are at a genetic disadvantage may, in certain circumstances, be more prone to neurosis than those who are better endowed. For example, Shields (4) has demonstrated that the less intelligent member of a binovular twin pair is also more neurotic. The presence of neurosis in one member of the twin pair may be secondary to his or her intellectual disadvantage or, conversely, the neurosis may be primary and the poor intellectual performance secondary. These possibilities are not mutually exclusive and both would be in accord with my concept of the neurotic maladaptive vicious cycle.

Dr. Ingram focuses on possible negative implications of what I have said, but I prefer to take a more positive view. For example, when a psychotherapist helps to eliminate a maladaptive vicious cycle in a patient, he or she may succeed in preventing more severe pathology, and a minimal intervention may therefore have a major impact.

In the final paragraph of my paper, I referred to the positive aspect of healthy adaptation. My focus on the maladaptive components was based on the need to be selective. Instead of elaborating on how the phylogenetic maladaptation of the individual leads to his or her ontogenetic maladaptation, one could have emphasized the positive aspect of adaptation by focusing on the mechanisms whereby phylogenetic adaptation promotes ontogenetic adaptation. I believe that there is ample evidence for this adaptive circle, which is precisely the converse of the maladaptive vicious cycle that I described. This could also be seen as a mechanism that promoted the action of natural selection by aiding the survival of the fittest.

When Dr. Ingram argues that "it is cynical in the absence of scientific evidence to speculate that we are determined more than the facts suggest," he shows a reluctance to apply evolutionary principles to human behavior. I suggest that the apparent absence of scientific evidence results merely from the limitations of space in my article. I have been impressed by the abundance of evidence for this theory emanating from various fields, including ethology, cultural anthropology, social psychology, etc. I agree with Dr. Ingram that our "genetic endowment . . . allows for much choice and freedom," and I believe that the ideas I have presented could enable us to marvel at the creativity of our genetic potential, both in terms of our individual development and our evolution as a species.

BOOK REVIEWS

Explorations in Child Psychiatry, *edited by E. James Anthony. New York, N.Y., Plenum Press, 1975, 493 pp., $25.00.*

This is quite an extraordinary book for the field of child psychiatry, one that I think is certain to become a classic. Its editor and principal author, E. James Anthony, M.D., who is Ittelson Professor of Child Psychiatry at the Washington University School of Medicine in St. Louis, Mo., should be warmly congratulated for his services to the field. In an address delivered to the Society of Professors of Child Psychiatry in 1973, Anthony reviewed the state of the art and science in this field. Although he delivered this address with his usual wit and erudition, he had some very grave warnings for the future of the field, such as the following: "Child psychiatry remains as service-oriented as ever . . . the art has flourished, but the science has stood still. . . . Efforts . . . must be made if this fragile discipline is to be salvaged." He has also pointed out that the lack of a vigorous, independent research tradition renders child psychiatry an anomaly in the medical field and suggests that we may get transplanted into the school of social work if we do not change our priorities.

Explorations in Child Psychiatry is an effort to assist in the needed change of priorities. Anthony contacted many of the best-known child psychiatrist researchers and asked them to write about their research careers—how and why they got into research and how their research development proceeded along both personal/existential and substantive/scientific dimensions. His goal in this endeavor was to make research a live, concrete, and attainable activity for child psychiatrists to identify with and emulate. Thus this book is a many-faceted mixture of historical, biographical, philosophical, technical, clinical, theoretical, and experiential aspects of research, almost all of which is interesting.

To give a sampling of some of the riches of this volume: papers by Louis Sander and Donald Cohen paint broad perspectives of the theory or natural philosophy of child psychiatry; Dennis Cantwell describes an excellent and comprehensive research model using the hyperkinetic syndrome; Stella Chess describes the experiential and family underpinnings of her renowned longitudinal study; and Reginald Lourie, Lauretta Bender, Hilde Bruch, M.W. Laufer, and Justin Call describe their research odysseys. Papers by Leon Cytryn, Ake Mattson, Edward Futterman, Eugene Arnold, and Joseph Fishoff describe a variety of types of clinical research. A number of papers, such as those by Theodore Shapiro and Gaston Blom, reflect the interest in and need for knowledge of other disciplines.

In short, the book offers a rich and varied assortment, a cornucopia of researchers, but that is only half of the value of the book. The other half consists of papers by James Anthony about research. In the first section of the book he contributes three papers written specifically for this book that deal with general perspectives, research as an academic function of child psychiatry, and the child as a research subject. This last, much neglected topic is especially well treated. Later in the book Anthony contributes a fine chapter on the "serious" experiment and methodology in child psychiatry. Finally, he includes two broad and perceptive lectures that touch on many aspects of research in child psychiatry.

Black Child Care: How To Bring Up a Healthy Black Child in America, *by James P. Comer, M.D., and Alvin F. Poussaint, M.D. New York, N.Y., Simon and Schuster, 1975, 394 pp., $9.95.*

"I'm black and that's a positive thing": this message is inherent both explicitly and implicitly in *Black Child Care* by Drs. Comer and Poussaint. Using a question-and-answer format, the authors cover the issues of child development and parent-child interaction from the time of conception through young adulthood. Although they provide an informative and easily read discussion of natural developmental issues for all children, the authors direct their attention to those who provide direct care and supervision for black children. They have succeeded admirably in their endeavor.

Historically, black children have been of incidental interest to authors discussing issues of child development. Black parents and caretakers have had to fend for themselves in their attempts to find answers that are particularly relevant to the developmental experience of the black child. Parents have had to rely on their own childhood experiences, many of which occurred at a time when the key issue was one of survival rather than one of developing, to the fullest extent possible, all of the capacities inherent within an individual. As a result many black parents and caretakers have not had the information base with which to help their children fully experience our changing society.

Racism is a reality; yet there are effective ways of dealing with this vicious issue. Black children must be taught to approach racism from a basis of knowledge, skill, and confidence. If children are to effectively confront racism, their most effective allies and teachers must be their parents and primary caretakers. Thus the needs that *Black Child Care* begins to address are quite evident. The volume is supportive of black parents in their past and present roles, but it also cajoles these parents toward active interaction with and advocacy for their children.

The authors cover many aspects of black existence both in the context of society at large and from the particular point of view of the black child. School, peer relationships, punishment, sex, violence and many other topics are approached in a frank and relevant manner. The authors indicate that a black child must know in detail what is going on and that this information, in order not to be overwhelming, must be communicated to the child from the earliest time in a calm and supportive manner. The key message to black parents is to begin this pattern of comunication early and to build on it

throughout the developmental experience of their children.

I reviewed this volume from two points of view—as a child psychiatrist involved in a teaching program and as a black parent of three children. As a psychiatrist, I note that *Black Child Care* is not a traditional psychiatric text, but for those whose training, experience, or work endeavors bring them into contact with black families there is a great deal of practical information not readily available in other places. If for no other reason than to be able to refer parents of black children to literature that will help them in understanding and interacting with their children, mental health professionals should familiarize themselves with this volume. As a black parent, I must simply thank the authors for a valuable contribution to the black developmental experience.

Sex After Sixty: A Guide for Men and Women for Their Later Years, *by Robert N. Butler, M.D., and Myrna I. Lewis, A.C.S.W. New York, N.Y., Harper & Row, 1976, 159 pp., $6.95.*

> "There is nothing I like better, Cephalus, than conversing with aged men: for I regard them as travellers who have gone a journey which I too may have to go, and of whom I ought to inquire whether the way is smooth and easy, or rugged and difficult. And this is a question I should like to ask of you who have arrived at that time which the poets call the 'threshold of old age.' Is life harder towards the end, or what report do you give of it?"
>
> "I will tell you, Socrates, what my own feeling is. Men of my age flock together; we are birds of a feather, as the old proverb says. At our meetings the tale of my acquaintances commonly is: 'I cannot eat, I cannot drink, the pleasures of youth and love are fled away. There was a good time once, but now it is gone and life no longer is life.' . . . But to me, Socrates, . . . if old age were the cause, I too (being old) and every other old man would have felt as they do. But this is not my experience, nor that of others whom I have known.
>
> "How well I remember the aged poet Sophocles' response to the question 'How does love sit with age, Sophocles: are you still the man you were?' 'Peace,' he replied. 'Most gladly have I escaped that of which you speak; I feel as if I had escaped from a mad and furious master.' " (1)

Obviously, Butler and Lewis do not view love as a mad and furious master but, rather, as an enhancer of life, an enjoyment not to escape from but to participate in until the very end. Obviously too, Butler, a Pulitzer Prize winner and the first director of the newly created National Institute on Aging, and Lewis have written a compassionate and informative "how to" book that should be comforting and encouraging to all of those who do not look at aging as a means of escape from sexual activity. It is a practical guide for the enjoyment of physical sex and pleasurable sensuality to whatever degree and in whatever way one wishes the satisfaction.

There are indeed two phases of the life cycle to which sexuality is denied: the very young, who "shouldn't," and the old, who "ought to know better." The reality is that the aged do know better. However, partners and sanction by society and family are ingredients not too readily obtainable or provided for by our value system. Butler and Lewis' slim and explicit volume provides the sanctions in a warm yet matter-of-fact manner and encourages the finding of a partner in spite of the disparate male to female ratio caused by the fact that women's life expectancy is greater than men's.

The chapters on overcoming common medical and emotional problems with sex, "Learning New Patterns of Love Making," "People Without Partners," and "Dating, Remarriage, and Your Children," are full of helpful hints. A chapter on "Where To Go for Help" is more explicitly directed to the men and women older than 60; indeed, most of the book is written for the layman.

"The Second Language of Love," the culminating chapter, is an eloquent advocation of the ultimate poignancy and joy inherent in sexual activity. This chapter is especially meaningful for me because I view the need for intimacy and touch and not necessarily for coitus as a biological need rooted in infantile experiences: "The sexual expressions of the elderly are numerous and diverse. . . . Much too often their feeble efforts to establish contactual relationship are misinterpreted and rejected, forcing the old to regressed behavior" (2).

It is the intent of Butler and Lewis to encourage the elderly to healthful sexual expression not only for its pleasurable, life-giving aspects but also to avoid regressive neurotic manifestations. They are to be commended for a frank, highly readable, and jargon-eschewing discourse on the joys of sex after the age of 60.

Chicago, Ill.

A Short Practice of Clinical Psychiatry, *by Russell Barton. Bristol, England, John Wright & Sons (Chicago, Ill., Year Book Medical Publishers, distributor), 1975, 413 pp., $29.95.*

This book, as the title implies, is a short compilation of the seminars, lectures, ward rounds, clinical demonstrations, and consultations that the author has given over a period of 25 years. Barton has used the material in this book to coach candidates for the Diploma in Psychological Medicine in England and the American Board of Psychiatry and Neurology examinations in the United States. He writes clearly, making explicit matters so often left implicit, and he follows the example of some excellent teachers who impressed him greatly, among them Sir Aubrey Lewis, whose clarity of thought and economy of words were a joy.

From the glossary on prevalence, treatment, and prognosis of 9 mental disorders outlined on the inside opening covers to the listing of 39 drugs commonly used in psychiatry in the United Kingdom in 1975 on the back covers, the author deals with his subject matter well and with an economy of words.

Readers of this journal who are thoroughly aware of the excellent psychiatric texts, encyclopedic in size, that are already available in the United States will find that this book is quite different. "For the sake of brevity," the author states, he has "deliberately excluded description of the way in

which mental disorders develop." He has also omitted discussion of many of the rarer illnesses, but he has added a segment recommending books dealing with such information.

There are short, succinct chapters on the various well-known mental disorders, and there is a brief but comprehensive treatment of psychodynamics and psychotherapy that deals with Freudian theory and the "mental mechanisms" plus a special consideration on how to make a psychodynamic formulation that includes examples. Pavlovian psychodynamic theory and behavior therapy are described, and brief sections consider group therapy, family therapy, supportive psychotherapy, and play therapy. As one can see from the topics dealt with, one virtue of this book is that it offers a handy review.

The chapters titled "Mental Deficiency" and "Mental Disorders of the Aged" should be mentioned, particularly the latter, which, although telescoped, is expertly done. Under the heading "Other Common Heartaches of the Elderly," Barton makes several cogent observations, such as,

> Wise people will stay where their roots and friends are. Familiar objects and places become important in late life. It is no kindness to elderly people to buy them a houseful of new furniture and pictures—"the old and tried and true" can be sadly missed.

There are appendices on history taking, patient inquiry forms, British law and psychiatry, and recording and conveying information as well as a rather truncated list of books recommended for further reading. In these days of required continuing education and threats of specialty reexamination, a short, concise volume like this one has a place if only as a review.

F.J.B.

Legal Challenges to Behavior Modification: Trends in Schools, Corrections and Mental Health, *by Reed Martin. Champaign, Ill., Research Press, 1975, 179 pp., $5.95 (paper).*

Our society is becoming increasingly concerned with the rights of individuals in institutions, especially schools, correctional agencies, and mental hospitals. The concern includes the person's right to treatment as well as his or her right to protection from arbitrary or unwarranted curtailment of freedom in the name of education, social rehabilitation, or treatment. The problem is present with any psychological treatment in a mental hospital and any educational effort in a school or correctional institution. However, the issue has been brought into sharp focus by the development of behavior modification because it is a powerful technology for altering behavior in specific and measurable ways.

The author of this slim but excellent book is a doctor of jurisprudence, a member of the bars of Texas and the District of Columbia, and Director of the Project on Law and Behavior in Washington, D.C., a nonprofit public interest group that examines the legal and human issues involved in providing psychological services in public institutions. *Legal Challenges to Behavior Modification* focuses on the trends in the law regarding such issues as due process, equal protection, accountability, and informed consent in regard to behavior modification programs in institutional settings.

Martin presents a sensitive and balanced approach to the difficult issues that arise in the context of societal needs, advances in behavioral sciences, and the rights of the individual. He correctly emphasizes that developments in the law and in the technology of behavioral change are not necessarily in conflict with each other. Indeed, recent changes in the law requiring schools to educate all handicapped and mentally retarded children arose in part because of convincing demonstrations that government agencies were by no means maximizing the functioning of such citizens by the application of currently available principles of behavioral science. Similarly, the emphasis in behavioral psychiatry on specifying goals of therapy that are mutually arrived at by the patient and his or her therapist is in keeping with a legal perspective that requires the contractual arrangement between patient and client or institution to be explicit and accessible to examination.

This book gives special attention to some behavior modification techniques, including aversive procedures, the use of tokens and tiers, "time-out" from a reinforcing environment as a behavior change method, and positive motivation strategies. It also deals with the thorny problem of the distinction between rights and privileges in institutional settings.

Of course this brief treatise does not provide comprehensive expositions or solutions to the many difficult and interrelated problems in this area. However, it does provide a clear and concise identification of the problems and some of the ways the developing law is dealing with them.

A particularly valuable aspect of the book is an annotated table of 20 key cases and judicial decisions that bear on many of these issues. These include *Clonce* v. *Richardson* (1) (depriving inmates of a federal prison of some of their institutional amenities in a behavior modification project), *Donaldson* v. *O'Connor* (2) (failing to provide adequate treatment when it is the justification for commitment), and *Morales* v. *Turman* (3) (extending the right to treatment to juveniles).

This informative and well-written volume will be of special value to those concerned with behavior modification in institutions. It will provide useful insights to all psychiatrists and those in related health professions who are concerned with treatment (behavior change) in any setting as well.

JOHN PAUL BRADY, M.D.
Philadelphia, Pa.

Moodswing: The Third Revolution in Psychiatry, *by Ronald R. Fieve, M.D. New York, N.Y., William Morrow & Co., 1975, 280 pp., $8.95*

In this book, obviously written for the layman, Dr. Fieve's thesis is,

> We are now undergoing our third and most spectacular revolution in the treatment of emotional states. In particular, we are witnessing for the first time a major chemical breakthrough with the lithium treatment and prevention of manic depression and recurrent depression.

Although many may agree that the first revolution in psychiatry was synonymous with the removal of chains from

madmen and madwomen by Pinel and that the second revolution can be attributed to the Freudian enlightenment, there are those who would argue that Fieve is too eager to define a third revolution on the basis of the "lithium breakthrough." The great success of psychopharmacological agents must be placed alongside the enormous developments related to social psychiatry, involving dehospitalization, community care, public health ideology, preventive intervention, epidemiology, and cross-cultural psychiatry.

At any rate, Fieve is convinced that depression is the most common psychiatric symptom for which people seek help and that its specific treatment in 80% or more of properly diagnosed cases is lithium carbonate. Many interesting cases are cited to support the thesis that "lithium is the first truly prophylactic agent in psychiatry to control, prevent, or stabilize the future lifetime course of a major mental illness."

The author relates mood swings to creativity, citing Abraham Lincoln, Theodore Roosevelt, and Winston Churchill, among many others, as victims of manic-depressive disorders. Many cryptic forms of manic depression are misdiagnosed, he states, because they masquerade as neurosis, schizophrenia, or organic brain syndrome. The United States, according to cited studies comparing us with Great Britain, is overdiagnosing schizophrenia and underdiagnosing depression. Thus many cases that would be amenable to rapid resolution with lithium are being sidetracked into psychotherapy, psychoanalysis, and other noneffective treatments, with consequent great loss of time, money, and healthy years. In particular, many persons who turn to alcohol and drugs are seen as suffering from depression. Fieve points out that often their dependency can be alleviated if their underlying affective swings can be moderated with lithium.

Many political figures of prominence, such as Eagleton and Forrestal, and many other influential people, such as business executives, educators, and artists, are struggling against mood swings. Because these people have power, the question is raised of psychiatric intervention in government and politics to control abnormal behavior or poor judgment based on affective disturbance. The complications and problems in bringing psychiatric input to bear on critical decisions of historic moment are discussed in detail.

Does psychotherapy work? Fieve asks. His answer is that, compared with lithium, in the depressions (bipolar and unipolar particularly), psychotherapy and psychoanalysis are disappointing, costly, time-consuming, and therefore not indicated. He also makes the case that Freud's famous Wolfman was really a manic-depressive and would be treated by lithium today with possibly much better results than Freud achieved after lengthy analysis.

Fieve also describes the operations of the metabolic ward and lithium clinic associated with the Psychiatric Institute of New York, N.Y. The ward has eight beds for intensive metabolic study of special cases, and the clinic is run with minimal psychiatric staff and offers considerable economic and therapeutic advantages over any other method of handling manic-depressive cases.

Finally, Fieve points out that lithium has unexplored possibilities in the long-term reduction of aggressive behavior, certain forms of alcoholism, some phobias, obsessive-compulsive and anxiety states, emotionally unstable behavior disorders of children and adolescents, and recurrent menstrual depression.

To summarize, this book is readable, interesting, informative to the lay reader, and carries little that is new to the sophisticate. It may be somewhat simplistic and overemphatic on the importance of lithium in the total scene. Its deprecation of psychotherapeutic techniques will elicit attack from some quarters. However, it carries a hopeful message to the average citizen and tells him or her that mental illness, like such physical illness as diabetes, may be based on the lack of a specific substance required by the body metabolism. It tells the reader that important progress is being made through psychiatric research and, I expect, leaves him or her with better regard for the potential of our field. In attempting to understand psychiatry and emotional disabilities through this book, the intelligent layman may feel a welcome relief from the subtleties and vagaries about mental diseases that impinge on him or her from many other sources.

MILTON GREENBLATT, M.D.
Sepulveda, Calif.

Bodily Communication, *by Michael Argyle. New York, N.Y., International Universities Press, 1975, 390 pp., $17.50.*

This book will be a most welcome addition to basic texts on nonverbal communication and body motion signal systems. Although there are many books on these subjects, there are probably none that can meet all of the varied needs of undergraduates, graduate students, specialists in the social sciences, and clinicians who require additional concepts and data about deviant systems.

The author is a well-known writer on numerous subjects in the fields of social psychology, including industrial relations and religion. Alone or with others he has written 12 books besides this one. These earlier studies have given him a wide perspective that is reflected in the content of *Bodily Communication* and in his selected bibliographies at the end of each chapter.

Because Argyle is keenly aware of the more recent developments in sociocultural anthropology, proxemics, comparative psychology, ethology, and social psychology in addition to the basic problems in nonverbal communication, speech, and formal linguistics, his book is a gold mine of information about many aspects of human communication. His suggestions regarding education, professional social skills, treating mental patients who have inadequate social skills, and training for intercultural encounters will be challenging to all who are looking for new methods of helping people do a better job of living. His brief comments on music's having several kinds of meaning with relation to visual imagery and movement responses, on the complex messages of drama, and on ritual as a means of expressing religious beliefs provide lively encouragement to all students of human behavior.

The book is divided into four parts: Biological and Cultural Background, The Different Uses of Bodily Communication, The Different Bodily Signals, and Conclusions and Wider Implications. There is an index for authors and for subjects plus 8 pages of photographs and some figure drawings that are helpful.

It is tempting in a field of such vast scope to search out several areas of excellence or deficiency for special comment. For clinicians the chapters "Bodily Communication in Human Society" and "Cultural Differences and Uniformities," which use case studies from Japan and the Arab world, may be particularly appealing. The more technical chapters on the expression of emotion, communicating interpersonal attitudes, sending information about personality, the different bodily signals, facial expression, gaze, gestures

and bodily movements, posture, bodily contact, spatial behavior, clothes and physique, and nonverbal vocalizations are clear expositions that should make both students and teachers happy.

The chapters on the use of nonverbal communication in social ritual and ceremony and nonverbal communication in politics and persuasion are splendid introductions to complex topics beyond language as such. Although they are also beyond the usual concerns of the clinic, hospital, or family or group practices, they are rewarding because they will help us become better observers and interviewers. The use of videotape and film and other devices is also mentioned.

This book can be highly recommended for its sound scholarship, broad vision, and easy reading on many difficult subjects to all students of language and nonverbal communication.

HENRY W. BROSIN, M.D.
Tucson, Ariz.

The Survivor: An Anatomy of Life in the Death Camps, *by Terrence Des Pres. New York, N.Y., Oxford University Press, 1976, 218 pp., $10.00.*

The Survivor stands in the line of books on the holocaust that attempt to understand, impart a meaning to, or take a message from the concentration camp experience. The author makes it clear that he is not directly concerned with the camps but, rather, with survival itself, "the capacity of men and women to live beneath the pressure of protracted crisis, to sustain terrible damage in mind and body and yet be there, sane, alive, still human." Des Pres bases his work on eyewitness accounts, most of which are from the German but some of which are from the Stalinist experience, and also on contributions from novelists, social scientists, and psychoanalysts. The book is written with passion and is well worth reading.

For Des Pres, the survivor is the new hero of our time. He has succeeded the tragic hero who defied death for the sake of his cause. The survivor turns away from death. His contribution to humanness is to live and thus to celebrate the wellsprings of life affirmation that reside in the biological roots of man. The survivor bears witness to what he has endured so that the world cannot ignore its descent into extremity.

For Des Pres, psychoanalytic explanations of concentration camp behavior cannot account for the survivor. He believes that psychoanalysis correctly assumes that "nothing is to be taken at face value," but he maintains that this dictum does not hold under the extreme conditions of the camps. There, behavior could have no meaning but itself; it is not susceptible to any kind of symbolic elaboration. Thus Des Pres particularly takes issue with Bruno Bettelheim's emphasis on the role of regression in camp life; he also denies such accepted conceptualizations as survivor guilt and identification with the aggressor.

Des Pres's point of view in this instance provides a welcome corrective to some attempts to exaggerate the importance of the psychopathological and to ignore the adaptive value of responses to concentration camp pressures. However, he is wrong in denying that psychological defenses played any role in inmate behavior. People in the camps varied widely in their makeups and the degree to which they were vulnerable to camp conditions. Furthermore, the camps themselves varied, from the bestialities of Buchenwald and Auschwitz to conditions in which hardships and oppression were very great but were not insupportable. On the basis of considerable experience in examining concentration camp survivors, I can attest to the ubiquity of feelings of guilt engendered in various ways by immersion in the emotional and physical cauldrons of the camps. Many of these survivors are still burdened by guilt feelings years later. Des Pres's refusal to admit the existence of "neurotic" mechanisms romanticizes the survivors by attributing to them a superhuman status.

The contention of the author that is hardest to accept is that survival in the camps depended primarily on the inmate's self-conscious choice of life at all costs rather than surrender to apathy and death. Furthermore, the choice is not seen as a commitment to live at all costs but, rather, to live with decency, to uphold the banner of civilization as this was manifested in the underlife of the camp beneath the apparent collapse of the larger civilization around it. This thesis deemphasizes the fact that to survive in the camps required actions on both the communal and the individual levels that were often the product of naked and savage self-interest but without which life could not have been sustained. Des Pres acknowledges that such actions took place, but the whole thrust of his book is to minimize their importance and frequency and to emphasize the altruism and solidarity of camp inmates. He does not and possibly cannot face the appalling fact that the most important determinants of survival in the camps were the state of one's health, the ability to make a temporary contribution to the German war effort, and sheer accident—where one happened to be when a selection for extermination was taking place or a guard felt like discharging his weapon at a human target. Certainly survival would have been impossible without efforts in common and a degree of ingenuity, energy, and determination, but in the face of the German resolve to destroy Jewish protoplasm these factors could have only a minor influence.

Whence comes the yearning, expressed not only in this admirable book but elsewhere, to endow victims with exceptional qualities? Perhaps it stems from the human hunger to believe, in spite of everything, that life must have meaning and that suffering cannot be utterly in vain.

PAUL CHODOFF, M.D.
Washington, D.C.

Giambattista Vico's Science of Humanity, *edited by Giorgio Tagliacozzo and Donald Phillip Verene. Baltimore, Md., Johns Hopkins University Press, 1976, 480 pp., $16.50.*

This volume is a compendium of Giambattista Vico's thoughts on the science of humanity. Prof. Frank Manuel, one of the 29 scholars who contributed essays to this book, states that Vico was a man out of place, rarely understood, a man now resurrected as part of the cultural *risorgimento* in modern Italy. Vico lived from 1668 to 1744. On the threshold of modernity, he had one foot rooted in the classics while the other broke the virgin ground of new ideas with his masterpiece *Scienza Nuova*. Vico is now recognized as a historiographer as renowned as his British contemporary Edward Gibbon. Both men saw in history a panorama of the future. Gibbon might have been writing of Vico when he said of Tacitus that he was "the first of historians who applied the science of philosophy to the study of facts."

It was the editors' intention that this wide-ranging series of essays provide the reader with a sample of the catalytic consequences of Vico's ideas. One is able to hear harmonics of

Vico's seminal ideas in the works of such disparate thinkers as James Joyce, Ludwig Wittgenstein, Jean Piaget, and Immanuel Kant. Vico's *verum-factum* principle posits, in essence, that the certainty of a truth is grounded in the fact that one has made that truth himself. In other words, man can know history because he created it.

The volume consists of five parts. The first section contains six essays inquiring into the development of Vico's philosophy, his discovery and acceptance of the idea that only he who has made things can truly know them. The second section consists of 4 essays on Vico's conception of history and historical knowledge. The third is a 9-essay analysis relating Vico's thought to the historians of philosophy. The fourth is a compilation of 5 essays dealing with the importance of Vico's thought for a humanistic conception of the social sciences, of man, and of society generally. The fifth section of the book consists of 4 essays that examine Vico's ideas on political doctrines.

Vico, founder of the philosophy of history, conceived the whole of history as a form of reality whose laws, conditions, and ultimate aims are a manifestation of mind. To Vico nothing is accidental; everything has significance; there is a fundamental unity of all scientific inquiry.

For modern psychiatry, the following quotation from Vico's *New Science* has a familiar ring:

> There must be in the nature of human institutions a mental language common to all nations which uniformly grasps the substance of things feasible in human social life and expresses it with as many diverse modifications as these same things may have diverse aspects.

Rochester, Minn.

Preschool IQ: Prenatal and Early Developmental Correlates, *by Sarah H. Broman, Paul L. Nichols, and Wallace A. Kennedy. Hillsdale, N.J., Lawrence Erlbaum Associates (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1975, 316 pp., no price listed.*

Putting men and other objects into space has been considered a major scientific breakthrough of the past quarter century. Among those interested in child development, the Collaborative Perinatal Project, which was nationwide in scope and involved 53,000 mothers and a follow-up of over 26,000 children from birth to the age of 7, was equally dramatic and worthwhile. *Preschool IQ*, basically a monograph, summarizes the history of the project data from the various participating institutions and presents conclusions related specifically to the correlation of IQ and a series of variables.

Although the critical facts of birth are in themselves important, the variables in white children having the highest correlations with IQ are those of maternal education and the socioeconomic index of the family. The mental test scores at 8 months are critical in evaluating IQ in black and white children but more so in the former. IQs were generally higher in intact families in which the mother had a good education and a good intellect. As noted in the conclusion, the major contribution of this particular study "lies in the extensive longitudinal data, primarily medical in content, which have been prospectfully collected on a very large, heterogeneous 'normal' population."

The data will be variably used and should affect not only medical care but public policy. Throughout the early part of this century there was an obvious need for the data that have been accumulated here. It is to be hoped that not only will the appeals of those who felt more data in this area were needed be answered but that the advocates will use what has been collected.

Preschool IQ is an outstanding source book.

HENRY H. WORK, M.D.
Washington, D.C.

The Mentally Retarded Child and His Family: A Multidisciplinary Handbook, revised ed., *edited by Richard Koch, M.D., and James C. Dobson, Ph.D. New York, N.Y., Brunner/Mazel, 1976, 532 pp., $15.00.*

This revised edition, like the first, which appeared in 1971, is intended to be used as a text for interdisciplinary courses; it is designed, according to the editors, "to be appropriate to any discipline which requires a broad understanding of the needs and problems of the mentally retarded." The first edition was well received, and the fact that the publisher has produced a revised edition after only 5 years suggests that the book is meeting a perceived need in an increasingly competitive market.

Lecturers who are using the first edition, as well as librarians who see it circulate, will want this updated version of *The Mentally Retarded Child and His Family*. However, purchasers should know that this second edition is less successful than the first was in defining the current state of the art. Of the 30 chapters, 2 are new and 5 others have been substantively revised to assimilate the advances of the past 5 years.

The 5 revised chapters are "Nursing Services" by Camille Legeay Cook, "Educational Services" by Jack Share, "Motivational Aspects of Mental Retardation" by Edward Zigler and David Balla, "Psychiatric Aspects of Retardation in Young Children" by Frank Menolascino, and "Utilization of Learning Principles in Retardation" by C.E. Meyers and D.L. MacMillan. The 2 new chapters are "Physical Therapy Services" by Janet Forinash, R.P.T., who concentrates on work with infants (up to age 3) at home, and "Concepts and Theory of Normalization," a hortatory address by William Bronston that was originally delivered at one of the congresses on Down's syndrome.

Some editorial improvements have been made in the remaining 23 articles, and in some instances a paragraph or two has been added. The chapter titled "Genetic Factors in Causation" contains new material on antenatal diagnosis and some new tables of inborn errors, but the 5 items added to the bibliography of this chapter do not include any of the major books in the field that have appeared since 1969.

The failure to update the bibliographies attached to many of the articles appears to me to be a significant defect in a book that calls itself revised, enlarged, and updated. Chapters in a textbook should include as references both the original articles specific to the data cited and the major hardcover literature to which a serious student can refer for more background.

One reason that this book does not quite keep pace with the times lies in the inclusion of several articles based primarily on specific studies that were recent and relatively less well known at the time of the first edition. The authors of these studies have not provided any postscripts. The community organization effort initiated in Los Angeles in the mid 1960s is still described with the optimism of a 2-year history;

Mercer's account of her now well-known labeling study on mental retardation as identified among Anglo, Mexican, and black populations in southern California still quotes (incompletely?) the American Association on Mental Deficiency definition used in its diagnostic manual in 1961 (1). Some of the continuing case reports from a children's hospital are still reported as in the same status and age as they were in 1968. Except for Share's chapter on education, there is scarcely a reference to the new litigation and its impact on the service delivery system for the mentally retarded.

Despite these deficiencies the book contains a great deal of readable material that stands the test of time; the faculty member who puts this book on his or her students' reading list will not lead them far astray.

The Annual of Psychoanalysis, Vol. III, *edited by the Chicago Institute for Psychoanalysis. New York, N.Y., International Universities Press, 1975, 436 pp., $17.50.*

The title of this volume might suggest to those not familiar with the series that it is an annual review of the year's significant literature on psychoanalysis, a sort of progress in psychoanalysis, or that it is a product primarily of the staff of the Chicago Institute for Psychoanalysis. It is neither. Its purpose, as stated in the first volume, is "to seek and publish good writings which focus on the theoretical and clinical aspects of psychoanalysis and, beyond that, over the full range of Freud's scientific humanism." It is directed toward psychoanalysts and also toward scientists and scholars in other disciplines, including the intelligent laity. It has been successful in its efforts because it offers articles of excellence that are in the mainstream of current psychoanalytic thought. This has attracted articles from a wide geographical distribution.

Volume III contains a series of essays, many of which have been published elsewhere, on seven aspects of psychoanalysis written by analysts from all over the world. Many are part of Festschriften, such as the papers presented in honor of Richard Sterba on his 75th birthday and those for Heinz Kohut on his 60th; other papers were presented or written for different occasions or reasons. I cannot in this limited space evaluate each article, but I hope that mentioning the authors and their topics will give the reader an idea of what to expect.

In section 1, Theoretical Studies, M. Basch gives an excellently detailed, critical presentation of Freud's "Project"; M. Hyman writes on libido theory; F. Sawyier presents a good down-to-earth discussion of empathy; and H. Thomä and H. Kächele present a thorough but technical study of methodology.

Section 2, Clinical Studies, includes 3 Festschrift articles honoring Richard Sterba, i.e., the late A. Bonnard's "The Parent's Psychic Reality as Part of the Child's Psychic Reality," P. Heimann's "Sacrificial Parapraxis—Failure or Achievement?" and S. Izner's "Dreams and the Latent Negative Transference"; H. Krystal's "Affect Tolerance"; P-n. Pao's "On the Diagnostic Term, 'Schizophrenia' "; and D. Terman's "Aggression and Narcissistic Rage: A Clinical Elaboration."

In section 3, Psychoanalytic Education, the late H. van der Sterren and H. Seidenberg present another article honoring Richard Sterba titled "The Problem of the Training Analysis."

Section 4, Psychoanalytic History, includes J. Beigler's discussion of Freud's treatment of the Rat Man; G. Pollock's very interesting "On Freud's Psychotherapy of Bruno Walter"; and E. Wolf and J. Gedo's equally interesting article on Montaigne.

Section 5, A Tribute, and an article in section 6, Psychoanalysis as Science, present Festschrift papers by J. Gedo and P. Parin honoring H. Kohut. Two of Kohut's papers are also presented in section 6.

Section 7, Applied Psychoanalysis, includes articles by J. Kavka on Oscar Wilde's narcissism; C. Kligerman's "Notes on Benvenuto Cellini," which also was written in Sterba's honor; and G. Pollock's "Mourning and Memorialization Through Music."

The general scientific level of thought and writing of these articles is high. Psychoanalysis has continued to use the essay style of Freud; it does not lend itself easily to abstracts or summaries. However, I think condensing one's ideas helps an author sharpen his or her article, aids in communication with the reader, and is therefore well worth the effort. In this work, only Kavka's article on Oscar Wilde has such an explicit summary.

A second suggestion that might benefit the reader of this series would be an introduction, however brief, to each volume to explain that it is neither an anthology nor a progress report.

Publishing costs are high, but it might be better to omit a chapter than yield to the custom of using fine print for explanations and especially for the verbatim quotes of patients. For example, every reader will be intrigued by Pollock's article on Freud's psychotherapy of Bruno Walter, the great conductor who was a friend of Gustav Mahler, and fascinated by Freud's brief therapy in this instance. However, Walter's own words are printed in paragraphs using such extremely fine print that it puts the reader off. This is an obstacle in other articles as well.

In conclusion, the content of this book is varied, interesting, and instructive, and anyone concerned with this field will read it with much pleasure and illumination.

An Atlas of Clinical Neurology, 2nd ed., *by John D. Spillane, M.D. New York, N.Y., Oxford University Press, 1975, 432 pp., $27.00.*

Is a picture worth 1,000 words? Ten thousand copies, translation into Japanese and Spanish, and a second edition of this atlas 10 years after the first answer a resounding yes. This volume began with a collection of thousands of photographs of patients accumulated by Dr. Spillane over 25 years. The text is held to a minimum; the patients' pictures are allowed to speak for themselves. The photographs are grouped in various but logical ways: by anatomy—"Head and Neck" and "The Limbs"; by disease—"Movement Disorders" and "Neurosyphilis"; and by function—"Posture and Gait" and "The Patient in Bed." The photography is su-

perb, as is the quality of printing. The legends supply pertinent clinical history, and the succinct text describes the diseases in lucid and urbane style.

Neurology remains a satisfying specialty in which careful observation of the patient is regularly rewarded. This volume is an ideal medium to elaborate on observations made at the bedside for the medical student and resident. Physicians preparing for qualifying examinations and the general physician who needs assistance with infrequently encountered neurological problems will find this a gold mine of information. This second edition deserves as much success as the first.

Mentally Ill Mothers and Their Children, *by Henry Grunebaum, Justin L. Weiss, Bertram J. Cohler, Carol R. Hartman, and David H. Gallant. Chicago, Ill., University of Chicago Press, 1975, 338 pp., $15.50.*

Even though there is an emphasis on the effects of mental illness in mothers on their children, this book goes well beyond the confines of its title and has many of the hallmarks of a classical study of the nature and treatment of disturbed mothering. The topic is sequentially explored by sharing the results of an innovative joint admission of disturbed mothers and their children to an inpatient psychiatric facility. Although this aspect of the study could itself justify the publication of this book, it is only a small sampling of the clinical and theoretical riches offered by the authors.

The interdisciplinary nature of the collaborative efforts of the five authors is at all times synthesized for the reader, whether the topical area is nursing approaches, administrative challenges, psychiatric management, or psychological research boundaries. Indeed, although the book is presented in five separate sections (Planning for Joint Admission; Psychiatric Nursing Perspectives; Children of Mentally Ill Mothers; Character, Mental Illness, and Mothering; and a Conclusion), the repeated consensus on topical areas of interest is quite remarkable and represents the fruits of long-term collaboration, careful attention to clinical realities, and mutual sharing of results with the reader.

The authors' experiences with joint admission of mother and child are clearly documented. Their generally positive results (including follow-up studies of their sample) strongly suggest that their experiences should be replicable in other clinical settings.

Although the sample size was relatively small, the clinical descriptions, courses in the hospital, and post-hospital experiences are clearly and thoroughly documented. For example, the in-depth view provided of the children of mentally ill mothers is masterful and stands in sharp contrast to the usual approach to large samples of children of very disturbed parents, i.e., providing only statistical data without the description of real experiences and their consequences. *Mentally Ill Mothers and Their Children* provides the anamnesis and current clinical data necessary to definitively explore the mother/father/child interrelationships and how they specifically impinge on the quality of parenting that the mentally disturbed mother is able to provide.

The book also contains numerous clinical vignettes that clearly illustrate the key psychiatric and developmental issues discussed. References are up-to-date and clearly related to the narrative in each of the five sections.

I think that this book illustrates clinical research at its very best. Accordingly, I would recommend it highly for all mental health personnel who are concerned with instances of disturbed mothering, its personal and interpersonal manifestations, and attempts to effectively manage it on behalf of both the parents and their children.

Primal Man: The New Consciousness, *by Arthur Janov, Ph.D., and E. Michael Holden, M.D. New York, N.Y., Thomas Y. Crowell Co., 1975, 522 pp., $10.00.*

In his second exposition of "primal theory," psychologist Arthur Janov proffers a series of chapters on the three levels of consciousness, the tripartite brain, the congruence between the "primal formulation" and the "latest in neurologic research," and how application of all these can reverse the destructive evolutionary process that pushes man into aggression and inhumanity. He is abetted in this effort by neurologist E. Michael Holden and, to a lesser extent, by anthropologist Bernard Campbell and psychologist Bernard McInerny.

Because most of the chapters were written to stand by themselves and because each seems to have been directed to a different readership, their haphazard mixing has produced a loose agglomerate that lacks cohesiveness and focus. Each chapter restates what the foregoing chapters have promulgated, with an occasional divergence or addition that hardly justifies the effort required to follow the incredible prolixity of the writing.

It would be unfair, of course, to judge the worth even of pseudoscience on the prose style of its apologists. At the same time, it would be irresponsible of a reviewer to ignore the paralogic that lies within the tortuous and convoluted phrasings of this book. Further, the uncritical reader might fail to appreciate the significance of the qualifications to what would, without such demur, emerge as extravagant claims. Circular reasoning is hardly unique to primal theorists, but few other psychologies have enlarged their circle to include cancer, heart disease, arteriosclerosis, and longevity as primary foci for their therapeutic applications.

Throughout the chapters there is a tendency to argue by analogy and, finally, to accept similarity as identity, to speculate that something *may* be so and then to base subsequent arguments on the assumption that it *is* so. Sometimes there is a shifting back and forth between contradictory speculations as the needs of the moment dictate. At other times the shift is from banal platitudes to overwhelmingly detailed lessons in neurophysiology. In ponderous asides, insight therapies are dismissed as providing only another level of resistance to consciousness of feelings and integration of "primal pain." Equally inadequate, according to the authors, are behaviorism, hypnotherapy, the "body therapy of the Reichians," reality therapy, Jungian therapy—indeed, any form of therapy other than primal therapy. According to Janov, insight therapy deals only with the intellectual-repressive left brain, and hypnotherapy deals only with the feeling-emotive right brain; only primal therapy facilitates integration of both sides.

Any therapy that claims to cure the major physical and mental ills not only of people but of the entire civilization as well is bound to excite broad interest. Psychiatrists are thus likely to be queried by their patients, their acquaintances,

and the media about the theory explicated in this book and the claims derived from it. They might therefore find it worthwhile to familiarize themselves with one or two chapters, even though the book itself might not warrant intensive or serious consideration.

Katonah, N.Y.

Medical Nemesis: The Expropriation of Health, *by Ivan Illich. New York, N.Y., Pantheon Books (Random House), 1976, 275 pp., $8.95.*

Medical Nemesis should be taken with a few grains of salt, although I fear this prescription for sodium chloride will be construed by the author as further evidence of the medical mafia's plot to medicalize the world. This is not a dispassionate review; try as I may, I fear I will review the man rather than the book. In the preface of this U.S. edition Mr. Illich slams a project I have been laboring at, the Club of Kos, an organization intended to be an international forum for medical values similar to the Club of Rome. Unfortunately, the sting of dismissal as a witless charlatan is a lasting one.

The burden of *Medical Nemesis* is that technologists, specifically medical technologists, have stolen mankind's birthright of free choice, specifically health, by dehabilitating rituals and taboos far beyond the ken and control of the common man. According to Illich the priest functionaries (doctors and drug men) of the established church (the medical profession) are so intent on maintaining their social-political power through their arcane knowledge that they willfully maim, sicken, debase, and dehumanize the people of the world.

It is not too difficult to speculate on the genesis of this exposé of the "scandalous-medical-influencing-machine." The book comes out of a think tank on a Mexican hillside where the gnostics gather to the guru. The think tank itself comes out of a Mexican monastery that in 1963 encouraged psychoanalysts from Mexico City to analyse its brothers. As a result, some of the brothers, the "talkers," developed a think tank for an assault on the affluent world, while others, the "doers," led by Gregoire Lemercier, used their personal analysis for a deeper dedication to relieving mankind's suffering (1). The latter moved farther up the mountain and founded Emau, a psychoanalytically oriented home for disturbed adolescents.

Illich runs through the familiar list of modern medicine's paradoxical, undeniable failures and implies that he is revealing a new gospel of therapeutic sin and hygienic heresy. Gradually it becomes clear that this is yet another antiestablishment witch-hunt. No one denies medicine's failures, but Illich is the first to conceive of them as the unrelieved work of the devil. The book concludes, "The true miracle of modern medicine is diabolical. It consists not only of making individuals but whole populations survive on inhumanly low levels of personal health."

Incidentally, the book is the work of many people. Even I had a hand in the manuscript during a visit to the think tank: I prevailed in deleting the idea that North American doctors were willfully withholding the *Merck Manual* (2) from distribution to the poor. It turned out that Mr. Illich's book dealer placed an incorrect order with the publisher. The one original contribution to this book is Valentina Borreman's excellent historical analysis of the concept of death.

I recommend *Medical Nemesis* for the same reason I would have recommended *Malleus Maleficarum* to physicians in 1498. It is well to study the power of the growing antiintellectual movement. Here is the quasirational underpinning for the forthcoming counterreformation against science. The new inquisition will appear as the Grand U.S. Health Plan now under construction by power-oriented lawyers, economists, and schemers in and about our government. When their unfulfilled promises come home to roost there must be an explanation why heaven failed to appear on earth; Mr. Illich and associates provide the local inquisitor with the neat and indisputable answer he or she will be looking for—it is the work of the devil. So on to the auto-da-fé.

Portland, Ore.

Des Idées de Jackson à un Modèle Organo-Dynamique en Psychiatrie (From Jackson's Ideas to an Organo-Dynamic Model in Psychiatry), *by Henri Ey. Toulouse, France, Edouard Privat, 1975, 301 pp., 51,20 French francs (paper).*

In Germany and France in the 1920s a renaissance of the ideas of J.H. Jackson (1835–1911) (1) took place. In 1928 a German translation of his Croonian lectures appeared, and its translator, Sittig, published his summary of Jackson's concepts in 1931 (2). Henri Ey and J. Rouart published their series of papers in 1936, and in 1938 they presented their monograph and translations of Jackson's works with an introduction by their professor, H. Claude. They might have agreed with Sittig that Jackson was the greatest thinker of neuropathology and that his rigorous and strict rules of research, analysis, and description are still examples of scientific exactitude and discipline.

The center piece of the current book is the 1938 monograph containing the translation of Jackson's paper "Factors of Insanity" (1, vol. II, pp. 411–421; originally published in 1894) and a paper on "Illusions" (1, vol. II, pp. 23–26; originally published in 1881). The notes running parallel in this work provide a commentary and an extension of the original text. Ey then presents a new system of psychiatry applying Jackson's ideas of evolution and dissolution. The system is composed of a ladder with eight steps: neurotic is the top step, then paranoid, oneiroid, dysesthetic, maniaco-melancholic, confusional-catatonic, schizophrenic, and, finally, demented structures. Ey does not offer a geometric scheme; the one Jackson presented (1, vol. II, p. 414) is conspicuously missing. This leaves us without aid in visualizing and/or imagining the ways of dissolution. Is the descent, once begun, an irrevocable one, or is restitution possible? All schemes of this kind have as much arbitrariness as a deduced order necessarily must. The advantages may be those that Jackson saw in the doctrine of evolution, which is "at once a means of scientific classification and a guide to discovery of new facts" (1, vol. II, p. 395).

In the third part of the book, The Organo-Dynamic Model, Ey presents his grand synthesis connecting the many parts of psychiatry as well as connecting psychiatry and neurology. Ey sees all great psychiatrists, in spite of their differences, as

working toward a unique and united psychiatry. He understands Jackson's concept of dissolution as equaling K. Jaspers' concept of process and Freud's description of alloplastic structures. There must be some truth in this sight, but I wonder if its gets us closer to the secrets of our main concern, the nature of mental illness.

Throughout the book Ey insists on dynamics. This is for him a way out of the oppressive determinism that seems to be so irritating for him in "mechanistic" psychology and psychiatry. There is no question that the term "dynamics" is the fata morgana of contemporary psychiatry and that Jackson's diads of evolution and dissolution, positive versus negative symptoms, and structural differences of higher and lower levels imply an exchange of energy ("dynamis").

Ey knows that he is writing an onthology, a philosophy of neurology and, principally, psychiatry. His main aim is to overcome the dualism he attacks so vigorously. He equates eloquently the dynamics of dissolution with the dialectics of positive and negative symptoms, leading us back to Jackson's stand of identity of phenomena observed from two sides, as if in this way the temptations of spiritualism and psychosomatic parallelism have been overcome. Here Ey becomes a vitalist, composing a new eclectical system. Whether we will be able to use it in our daily work remains questionable. In Henri Ey's hands it probably works.

The Cycles of Sex, *by Warren J. Gadpaille, M.D.; edited by Lucy Freeman. New York, N.Y., Charles Scribner's Sons, 1975, 472 pp., $17.50; $6.95 (paper).*

Dr. Gadpaille has presented an extremely comprehensive and detailed coverage of the developmental aspects of sexuality, practically from implantation to the grave. He says that "sex begins in the womb," i.e., that sexual differentiation begins there, and proceeds to give us a succinct, clear summary of "thousands of research studies by hundreds of scientists over a number of decades."

Dr. Gadpaille goes on to more widely considered periods of sexual development, from the "all-encompassing influences during the first 18 months" to the "countdown to the biological implosion" (puberty). He has incorporated extensive research findings—both recent and of the past—and, on occasion, confuses the two. For example, he states, "Recent research has clearly corroborated the correlation between the quality of maturing and the presence or absence of overt genital sexuality in infants," citing as the reference René A. Spitz's 1949 article "Autoeroticism: Some Empirical Findings and Hypotheses."

In his preface, Dr. Gadpaille tells us that his book is addressed to two audiences: "The broadest consists of parents, teachers, and clergymen. . . . However, I have been primarily a writer for other professionals." One wonders whether the profession he has in mind is psychiatry, and, if so, whether it is necessary to identify Sigmund Freud as "the pioneer Viennese psychoanalyst." The book incorporates some considerably detailed data that would be presumed to be basic and fundamental to the discipline of psychiatry. With this caveat in mind, I found the book to be almost encyclopedic for medical students, mental health workers, clergymen, and others interested in a well-documented compilation of "the facts of life."

The tone of the book is almost invariably upbeat. The style is excellent. The writing is of a high caliber, flowing smoothly over familiar ground from beginning to end. The author credits his editorial collaborator, Lucy Freeman, for making this book pleasantly readable. It certainly is that.

HARVEY BLUESTONE, M.D.
Bronx, N.Y.

The Gifted Child, *by Cyril Burt. New York, N.Y., Halsted Press (John Wiley & Sons), 1975, 209 pp., $14.75.*

This is a posthumous book of Dr. Cyril Burt, a well-known English educational psychologist. In an article reprinted from the *American Psychologist* in 1972, Dr. Burt indicates some of the evidence for inheritance of intelligence. He interprets his results as showing that the genetic component in intelligence is greater than the environmental component. For one of his contrast groups he uses both his own data and those of other investigators on siblings raised apart. A second important point is Burt's indication of the loss of talent among gifted children when such talent is unrecognized, discouraged, or goes to waste for other reasons. Finally, he shows that the intellectually gifted are also superior in physical health, strength, and psychological adjustment, in contrast to the stereotypical picture of the maladjusted bookworm.

Unfortunately, these points are presented in a format that can be compared to a symposium by a single author. Burt snatches previous articles, arguments, counterarguments, poetry, limericks, surveys, and cases from here, there, and everywhere and pastes them into a collage. His approach is relatively intemperate.

Potential readers who expect to learn about giftedness in children will, for the most part, be disappointed because children are discussed for the first time roughly three-fourths of the way through this book. *The Gifted Child* contains interesting, useful, and humanitarian material. I wish it had been better written.

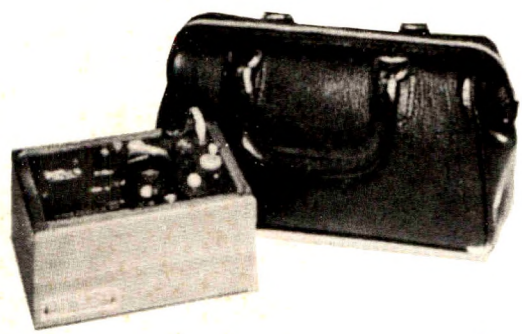
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.

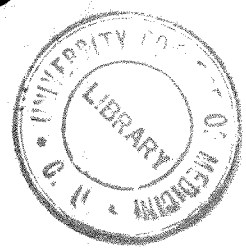
AMERICAN PSYCHIATRIC ASSOCIATION

Basic tools of primitive psychiatry



Mankpo: Sceptres or staffs used by the Heviosso (lightning God) cult in medical ceremonies among the Ewe of Tongo and Fon of Dahomey. *Right,* staff with leopard's head, bared teeth and tongue (Ewe, Togo). *Left,* staff with ram's head—the sacred animal of the Heviosso—in the form of a serpent symbolizing the fire-spitting rainbow God of healing (Fon, Dahomey). From the collection of the Segy Gallery, New York City.

Basic tool of Western psychiatry

Thorazine®

Tablets: 25 and 50 mg of the HCl

(chlorpromazine, SK&F)

- 'Thorazine' controls psychotic symptoms
- Especially useful in agitated, violent or anxious schizophrenic patients
- Unsurpassed clinical experience
- 18 convenient dosage forms and strengths

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications

Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of manifestations of psychotic disorders. For control of the manifestations of manic-depressive illness (manic phase).

Probably effective: For the control of moderate to severe agitation, hyperactivity or aggressiveness in disturbed children.

Possibly effective: For control of excessive anxiety, tension and agitation as seen in neuroses.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose states, presence of large amounts of C.N.S. depressants, or bone marrow depression.

Warnings:

Caution is recommended when 'Thorazine' is administered for the treatment of vomiting in children.

Antiemetics are not recommended to treat uncomplicated short-term vomiting in children or vomiting of unknown etiology.

The possibility of extrapyramidal reactions from 'Thorazine' may confuse the diagnosis of Reye's syndrome or other encephalopathy. Although unconfirmed, some suspicion exists that centrally-acting antiemetics may contribute to or adversely affect the course of Reye's syndrome, and should be avoided in suspected cases.

Avoid using in patients hypersensitive (e.g., blood dyscrasia, jaundice) to any phenothiazine. Caution patients about activities requiring alertness (e.g., operating vehicles or machinery) especially during the first few days' therapy. Avoid concomitant use with alcohol. May counteract antihypertensive effect of guanethidine and related compounds.

Use in pregnancy only when essential. There are reported instances of jaundice or prolonged extrapyramidal signs in newborn whose mothers had received chlorpromazine.

Precautions: Use cautiously in persons with cardiovascular, liver or chronic respiratory disease, or with acute respiratory infections. Due to cough reflex suppression, aspiration of vomitus is possible. May prolong or intensify the action of C.N.S. depressants, organophosphorus insecticides, heat, atropine and related drugs. (Reduce dosage of concomitant C.N.S. depressants.) Anticonvulsant action of barbiturates is not intensified. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Discontinue high-dose, long-term therapy gradually.

Patients on long-term therapy, especially high doses, should be evaluated periodically for possible adjustment or discontinuance of drug therapy.

Adverse Reactions: Drowsiness, cholestatic jaundice, agranulocytosis, eosinophilia, leukopenia, hemolytic anemia, thrombocytopenic purpura and pancytopenia; postural hypotension, tachycardia, fainting, dizziness and, occasionally, a shock-like condition; reversal of epinephrine effects; EKG changes have been reported, but relationship to myocardial damage is not confirmed; neuromuscular (extrapyramidal) reactions; pseudo-parkinsonism, motor restlessness, dystonias, persistent tardive dyskinesia, hyperreflexia in the newborn; psychotic symptoms, catatonic-like states, cerebral edema; convulsive seizures; abnormality of the cerebrospinal fluid proteins; urticarial reactions and photosensitivity, exfoliative dermatitis; contact dermatitis; lactation and breast engorgement (in females on large doses), false positive pregnancy tests, amenorrhea, gynecomastia; hyperglycemia, hypoglycemia, glycosuria; dry mouth, nasal congestion, constipation, adynamic ileus, urinary retention, miosis, mydriasis; after prolonged substantial doses, skin pigmentation, epithelial keratopathy, lenticular and corneal deposits and pigmentary retinopathy, visual impairment; mild fever (after large I.M. dosage); hyperpyrexia; increased appetite and weight; a systemic lupus erythematosus-like syndrome; peripheral edema.

NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 10 mg., 25 mg., 50 mg., 100 mg. and 200 mg., in bottles of 100; Single Unit Packages of 100 (intended for institutional use only). Spansule® capsules, 30 mg., 75 mg., 150 mg., 200 mg. and 300 mg., in bottles of 50; in Single Unit Packages of 100 (intended for institutional use only). Injection, 25 mg./ml.; Syrup, 10 mg./5 ml.; Suppositories, 25 mg. and 100 mg. Concentrate (intended for institutional use only), 30 mg./ml. and 100 mg./ml.

THEME AND VARIATIONS: A BEHAVIOR THERAPY CASEBOOK
By Joseph WOLPE, M.D., Temple University and Eastern Pennsylvania Psychiatric Institute

Dr. Joseph Wolpe, author of the best seller, THE PRACTICE OF BEHAVIOR THERAPY, 2nd edition, has compiled this important new book as either a companion volume to his textbook or for independent use in courses utilizing the case study approach.

Contents:

I. INTRODUCTION. Chapter 1: Perspectives and Objectives.

II. CONCEPTUAL AND EXPERIMENTAL BASES. Chapter 2: The Reciprocal Inhibition Theme and the Emergence of Its Role in Psychotherapy. Chapter 3: The Case History of a Neurotic Cat.

III. BEHAVIOR ANALYSIS AND EARLY INTERVENTIONS. Chapter 4: Initial Behavior Analysis in Anxiety Neurosis with Depression and Despair. Chapter 5: A Demonstration and Discussion of Information-Gathering and Strategy-Planning in an Anxiety Neurosis. Chapter 6: Initial Behavior Analysis in a Case of Depression. Chapter 7: Identifying the Antecedents of Agoraphobia. Chapter 8: Instigating Assertive Behavior.

IV. LONGITUDINAL ACCOUNTS OF BEHAVIORAL TREATMENT. Chapter 9: Interpersonal Inadequacy and a Separate Insomnia Syndrome: Two Conferences at Different Stages of Treatment. Chapter 10: Avoidance of Marital Commitment. Chapter 11: An Unusual Syndrome of Indecent Exposure. Chapter 12: A Case of Neurodermatitis. Chapter 13: A Multi-Faceted Psychosomatic Case.

		0 08 017089-7	**h**	**12.50**

BEHAVIOR THERAPY IN PSYCHIATRIC PRACTICE: THE USE OF BEHAVIORAL PROCEDURES BY PSYCHIATRISTS
Edited by Joseph WOLPE, M.D., and Leo J. REYNA, Boston University

In this, the first of a series of volumes on "Behavior Therapy in Psychiatric Practice," nearly forty articles authored or co-authored by psychiatrists from 1970 to 1975 in the **Journal of Behavior Therapy and Experimental Psychiatry** have been selected.

256 pp	**1976**	**0 08 021147-X**	**f**	**$ 9.25**
		0 08 021148-8	**h**	**13.50**

PRESCRIPTIVE PSYCHOTHERAPIES
By Arnold P. GOLDSTEIN and Norman STEIN, Syracuse University

Presents a comprehensive attempt to individualize psychotherapy; to tailor the properties of treatment to specific patient characteristics and to make the selection of both the therapeutic approach and the therapist fit characteristics of the patient.

A dual focus is presented:

1. How to conduct psychotherapy research which leads to more effective therapeutic prescriptions.
2. An extended series of currently useful clinical prescriptions based upon extensive review of current research.

The overall goal is to specify the interactions between patient, therapist, and treatment variables that produce differential therapeutic outcomes.

		0 08 019506-7	**h**	**16.00**

PHYSICAL DISABILITY AND HUMAN BEHAVIOR, second edition
By J. W. McDANIEL, School of Medicine, University of Colorado

"...timely and indeed welcomed study by an eminent and respected American Neuropsychologist."
From a review of the first edition in Clinical Paediatrics

"I found Dr. McDaniel's book the best single source of overview material on the psychology of physical disability that I have reviewed to date."
Herbert G. Steger, Ph.D.
University of California, Irvine

173 pp	**1976**	**0 08 019721-3**	**f**	**$ 5.25**

Information for Contributors

SUBMISSION OF MANUSCRIPTS

Manuscripts should be submitted in duplicate to Francis J. Braceland, M.D., Editor, *The American Journal of Psychiatry*, 1700 Eighteenth Street, N.W., Washington, D.C. 20009. Authors of numbered papers presented at the Association's annual meeting should submit two copies of the manuscript to the secretary of the session or notify the secretary that the manuscript will be sent to the *Journal* office later.

All numbered annual meeting papers become the property of the *Journal* although, due to space limitations, fewer than half can be published in the *Journal*. Release of a manuscript for publication elsewhere must be secured from the Editor.

Communications about a manuscript, by letter or telephone, should include reference to the manuscript number. In the case of annual meeting papers, this is the number carried in the program booklet; with other manuscripts, it is the number noted in the letter acknowledging receipt of the manuscript.

GENERAL POLICIES

Manuscripts are accepted for consideration with the understanding that they represent original material and that they are not being considered for publication elsewhere. Once a paper has been published in the *Journal*, which is a copyrighted publication, the legal ownership of all parts of the paper, including any illustrations, passes from the author to the *Journal*. If an individual or organization wishes to reprint material published in the *Journal*, written permission must first be secured from the APA Publications Services Division, 1700 Eighteenth St., N.W., Washington, D.C. 20009; there will usually be a charge for granting this permission.

Informed consent. Manuscripts that report the results of experimental investigation on human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure had been fully explained.

Manuscripts are accepted on condition that the Editor be given the right to make revisions aimed at greater conciseness and clarity and to bring the manuscript into conformity with *Journal* style regarding capitalization, punctuation, etc.

All measurements must be in metric units.

The *Journal* does not hold itself responsible for statements made by contributors. Unless so stated, material in the *Journal* does not reflect the official attitude or position of the American Psychiatric Association or of the *Journal's* Editorial Board.

SPECIFICATIONS FOR MANUSCRIPTS

Manuscripts should be typed in upper and lower case on one side only of letter-size bond (or other opaque) paper. All parts of the manuscript (including case reports, footnotes, references, etc.) should be double-spaced, with generous margins. Subheads should be inserted at reasonable intervals. Abbreviations not easily recognized by the average reader should be explained.

Length. As a general rule the manuscript of a regular article should not exceed 10–12 typed pages, unless a special arrangement has been made with the Editor; Brief Communications should not exceed 8 typed pages. Letters to the Editor should not exceed 500 words unless a special arrangement has been made with the Editor.

Author identification. The authors' affiliations and position titles should be provided and an address and telephone number given for the first-named author or the coauthor who has been designated to assume responsibility for the paper and reprint requests. The number of authors should be limited to principal researchers and writers, with other collaborators being acknowledged in a footnote.

Precis. A brief precis is included at the beginning of each article: 60–100 words for regular articles, 40–60 words for Brief Communications. The author may prepare the precis himself or ask that the *Journal* staff prepare it.

References. References should be typed double-spaced on a separate sheet of paper, to be attached at the end of the manuscript. They should be arranged according to their order of appearance in the text, where they should be indicated by numbers in parentheses. Reference citations should be restricted to closely pertinent papers; a complete review of the literature is rarely desirable, except in the case of review articles for which a special arrangement has been made with the Editor.

References should be typed in accordance with the style shown below for books and journal articles; chapters in books will be treated as journal articles with regard to capitalization. Up to three authors should be listed; one or more authors past the third will be designated "et al." Abbreviations of journal names should conform to the syle used in *Index Medicus*.

1. Berne E: Principles of Group Treatment. New York, Oxford University Press, 1966, p 26
2. Schildkraut JJ: Tranylcypromine: effects on norepinephrine metabolism in rat brain. Am J Psychiatry 126:925–931, 1970
3. Blackwell B, Marley E, Price J, et al: Hypertensive interactions between monoamine oxidase inhibitors and foodstuffs. Br J Psychiatry 113:349–365, 1967
4. Brosin H: Communication systems of the consultation process, in The Psychiatric Consultation. Edited by Mendel W, Solomon P. New York, Grune & Stratton, 1968, pp 1–12

Tables and figures. Tables and figures should be self-explanatory and should supplement, not duplicate, the text. See recent issues of the *Journal* for the general requirements of style.

Each table should be typed on a separate sheet, attached at the end of the manuscript. The data should be arranged so that columns of like material read down, not across.

A complete set of figures, preferably in the form of glossy prints, should accompany each of the two copies of the paper. Most figures will be reduced to about 3¼ inches in width; all elements of a figure should be prepared to withstand this reduction. Graphs should be finished drawings not requiring further artwork. Authors are urged to engage the services of a professional in the preparation of figures. Authors may be required to meet the costs of any further artwork that must be done in the editorial office.

AUTHORS' CORRECTIONS

After the paper has been scheduled for publication, the edited manuscript will be sent to the first-named author for corrections and answers to queries. Prompt return is necessary to ensure publication in the assigned month. If an author expects to be away from his office for a long period of time after being notified of the acceptance of his paper, he should inform the *Journal* office or arrange with a coauthor to assume responsibility for the paper. Galley proofs will not be sent to authors.

REPRINTS

No reprints are furnished gratis. An order form for reprints will be sent to authors prior to publication of their papers. Reprints are usually mailed to authors about a month after publication of the article. Requests from others to order reprints should be directed to the Editor; inclusion of a letter of permission from the senior author and a brief statement of the intended use of the reprints will expedite the processing of such requests.

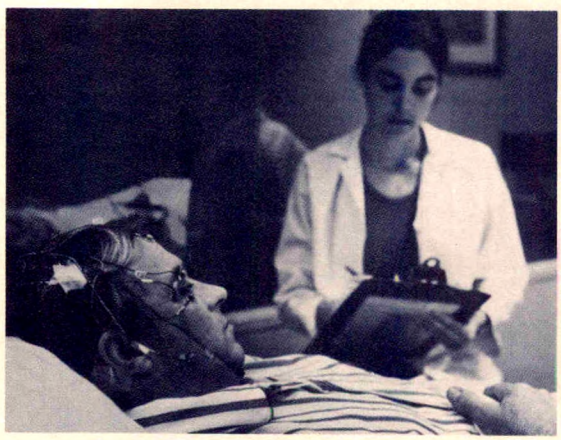
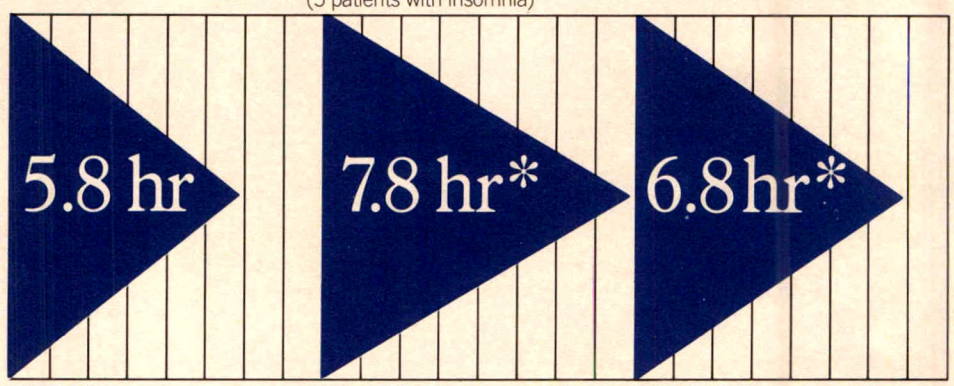
From the sleep research laboratory:



Dalmane® (flurazepam HCl) proved the most effective hypnotic over 14 nights...[1]

14 consecutive nights:
3 in sleep laboratory, 8 at home,
3 in sleep laboratory

...and now, the only one prove effective over 28 nights.[2,3]



28 consecutive nights:
3 in sleep laboratory, 7 at home,
4 in sleep laboratory, 10 at home,
4 in sleep laboratory[3]

For those patients who need it, Dalmane (flurazepam HCl) alone provides continued effectiveness[2,3]

Since insomnia is often transient and intermittent, the prolonged administration of a hypnotic is generally not necessary or recommended. But for those patients whose insomnia is a chronic problem, the continued effectiveness of Dalmane is a decided benefit. Even at the end of a 28-night medication period, patients with chronic insomnia were falling asleep faster, spending less time awake during the night, and sleeping substantially longer on Dalmane 30 mg *h.s.* than on baseline placebo nights (average results). This effectiveness was proved[2] and confirmed[3] in two independent sleep research studies using a new 47-night protocol. When similarly evaluated, pentobarbital was ineffective at the end of two weeks.[2]

TOTAL SLEEP TIME (MEAN)[3]
(5 patients with insomnia)

*Significantly increased over baseline placebo ($P<.05$).

In previous studies,[1] chloral hydrate and glutethimide lost most or all effectiveness

In fact, continued effectiveness for both inducing and maintaining sleep over 14 consecutive nights[1] has long been an exclusive benefit of Dalmane. No other available sleep agent, including chloral hydrate or glutethimide,[1] has been able to demonstrate such effectiveness in the sleep research laboratory.

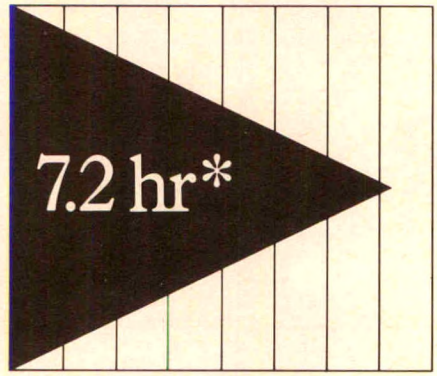
The safety record of Dalmane (flurazepam HCl) is well established

Dalmane is relatively safe and well tolerated. Prolonged administration is not generally necessary, but if used repeatedly, periodic blood counts and liver and kidney function tests should be performed.

Dalmane®
(flurazepam HCl)

ROCHE

relatively safe... no need to increase dosage.



Please see following page for a summary of complete product information.

1,5,7,14,28 nights... as needed, the effectiveness of **Dalmane**® one *h.s.* (flurazepam HCl) Ⓒ IV meets the challenge of insomnia

One 30-mg capsule *h.s.*—usual adult dosage (15 mg may suffice in some patients).
One 15-mg capsule *h.s.*—initial dosage for elderly or debilitated patients.

- **Patients fall asleep rapidly, sleep longer on a single *h.s.* dose.**
- **Nighttime awakenings and time spent awake are reduced**
- **Effectiveness maintained without dosage increase from night to night**
- **Patients generally awaken refreshed; morning "hangover" is infrequent**

TOTAL SLEEP TIME (OVERALL MEAN)[3]
(5 patients with insomnia)

DALMANE (flurazepam HCl)
NIGHTS 1-3, 12-14, 26-28
*Significantly increased over baseline placebo ($P < .05$).

REFERENCES:

2. Kales A, *et al*: *Clin Pharmacol Ther* *18*:356-363, Sep 1975
3. Dement WC, *et al*: Long-term effectiveness of flurazepam 30 mg *h.s.* on chronic insomniacs. Presented at the 15th annual meeting of the Association for Psychophysiological Study of Sleep, Edinburgh, Scotland, Jun 30-Jul 4, 1975

Before prescribing Dalmane (flurazepam HCl), please consult complete product information, a summary of which follows:

Indications: Effective in all types of insomnia characterized by difficulty in falling asleep, frequent nocturnal awakenings and/or early morning awakening; in patients with recurring insomnia or poor sleeping habits; in acute or chronic medical situations requiring restful sleep. Since insomnia is often transient and intermittent, prolonged administration is generally not necessary or recommended.

Contraindications: Known hypersensitivity to flurazepam HCl.

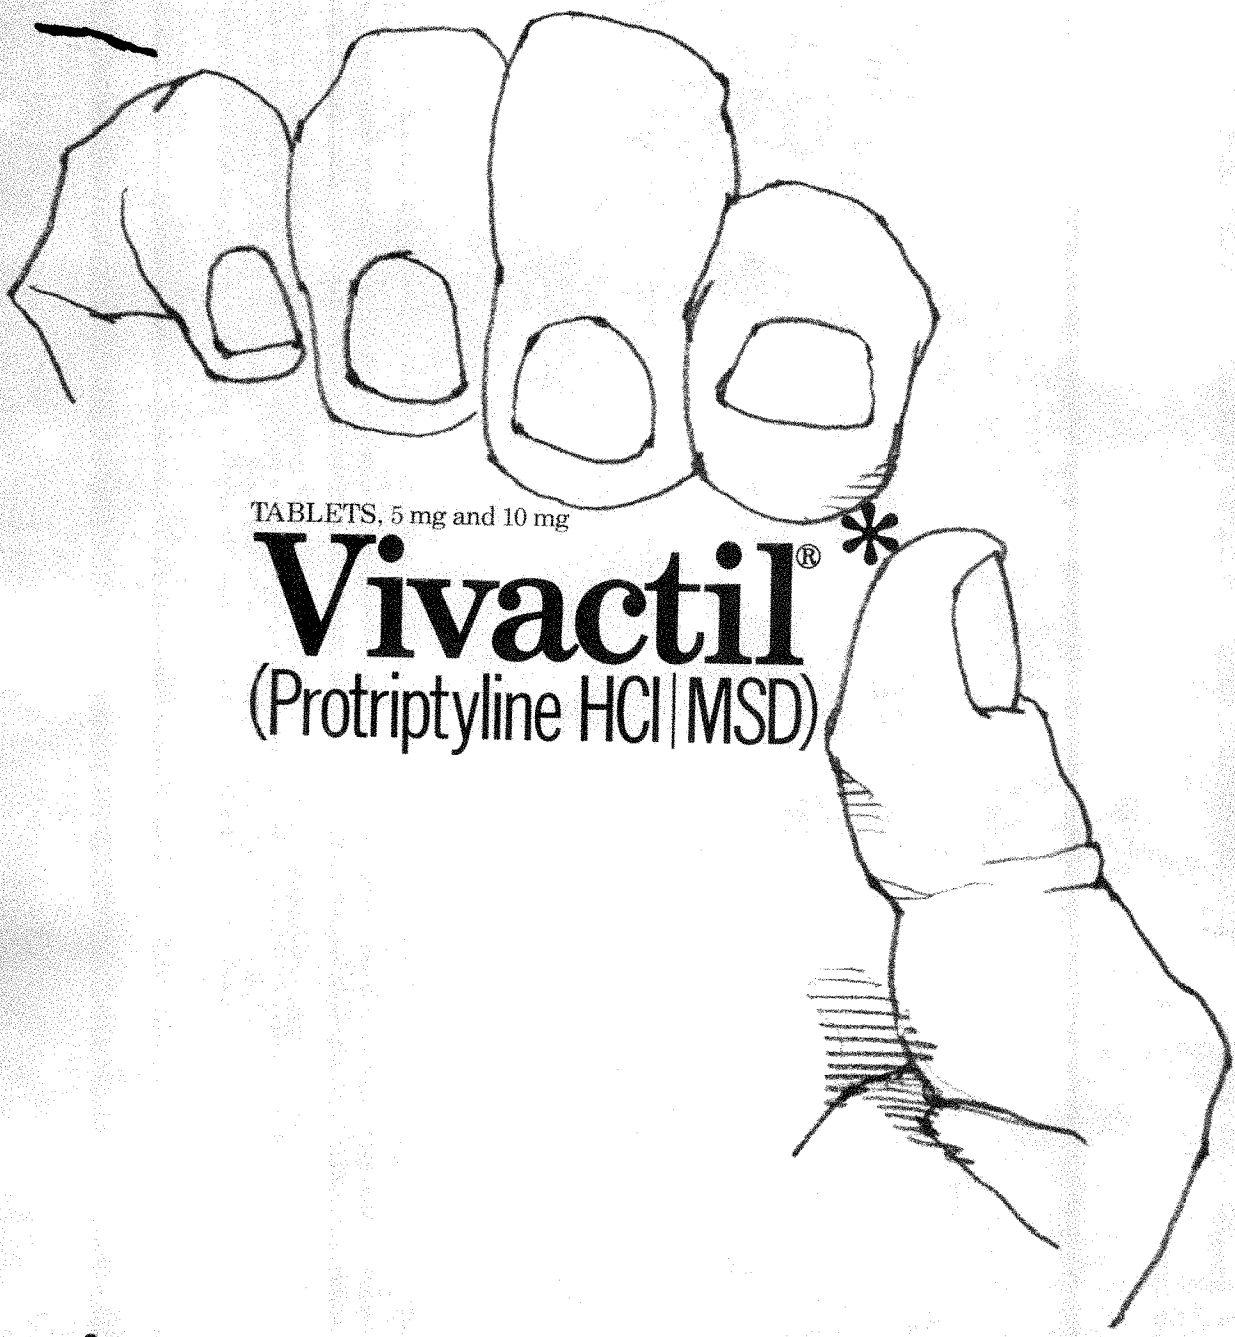
Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. Caution against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving).

Usage in Pregnancy: **Several studies of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) suggest increased risk of congenital malformations during the first trimester of pregnancy. Dalmane, a benzodiazepine, has not been studied adequately to determine whether it may be associated with such an increased risk. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Not recommended for use in persons under 15 years of age. Though physical and psychological dependence have not been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage.

Precautions: In elderly and debilitated, limit initial dosage to 15 mg to preclude oversedation, dizziness and/or ataxia. Consider potential additive effects with other hypnotics or CNS depressants. Employ usual precautions in patients who are severely depressed, or with latent depression or suicidal tendencies. Periodic blood counts and liver and kidney function tests are advised during repeated therapy. Observe usual precautions in presence of impaired renal or hepatic function.

Adverse Reactions: Dizziness, drowsiness, lightheadedness, staggering, ataxia and falling have occurred, particularly in elderly or debilitated patients. Severe sedation, lethargy, disorientation and coma, probably indicative of drug intolerance or overdosage, have been reported. Also reported: headache, heartburn, upset stomach, nausea, vomiting, diarrhea, constipation, GI pain, nervousness, talkativeness, apprehension, irritability, weakness, palpitations, chest pains, body and joint pains and GU complaints. There have also been rare occurrences of leukopenia, granulocytopenia, sweating, flushes, difficulty in focusing, blurred vision, burning eyes, faintness, hypotension, shortness of breath, pruritus, skin rash, dry mouth, bitter taste, excessive salivation, anorexia, euphoria, depression, slurred speech, confusion, restlessness, hallucinations, paradoxical reactions, *e.g.*, excitement, stimulation and hyperactivity, and elevated SGOT, SGPT, total and direct bilirubins and alkaline phosphatase.



Dosage: Individualize for maximum beneficial effect. *Adults:* 30 mg usual dosage; 15 mg may suffice in some patients. *Elderly or debilitated patients:* 15 mg initially until response is determined.

Supplied: Capsules containing 15 mg or 30 mg flurazepam HCl.

.In clinically significant depression

TABLETS, 5 mg and 10 mg

Vivactil®*

(Protriptyline HCl | MSD)

***When you want an antidepressant that is characteristically nonsedating for the patient under close medical supervision (Symptoms such as anxiety or agitation may be aggravated.)**

MSD
MERCK SHARP & DOHME

For a brief summary of prescribing information please see following page.

In clinically significant depression

TABLETS, 5 mg and 10 mg

Vivactil®

(Protriptyline HCl | MSD)

Contraindications: Known hypersensitivity; acute recovery phase following myocardial infarction. Should not be given concomitantly with an MAOI; hyperpyretic crises, severe convulsions, and deaths have occurred in patients receiving tricyclic antidepressant and MAOI drugs simultaneously. When it is desired to substitute protriptyline HCl for an MAOI, a minimum of 14 days should be allowed to elapse after the latter is discontinued. Protriptyline HCl should then be initiated cautiously with gradual increase in dosage until optimum response is achieved.

Warnings: May block the antihypertensive effect of guanethidine or similarly acting compounds. May impair mental and/or physical abilities required for the performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Should be used with caution in patients with a history of seizures and, because of its autonomic activity, in patients with a tendency to urinary retention or increased intraocular tension.

Tachycardia and postural hypotension may occur more frequently than with other antidepressant drugs. Should be used with caution in elderly patients and patients with cardiovascular disorders; such patients should be observed closely because of the tendency of the drug to produce tachycardia, hypotension, arrhythmias, and prolongation of the conduction time. Myocardial infarction and stroke have occurred with drugs of this class. On rare occasions, hyperthyroid patients or those receiving thyroid medication may develop arrhythmias when this drug is given.

Usage in Children: Not recommended for use in children because safety and effectiveness in the pediatric age group have not been established.

Usage in Pregnancy: Safe use in pregnancy and lactation has not been established; therefore, use in pregnant women, nursing mothers, or women who may become pregnant requires that possible benefits be weighed against possible hazards to mother and child.

Precautions: When protriptyline HCl is used to treat the depressive component of schizophrenia, psychotic symptoms may be aggravated; likewise, in manic-depressive psychosis, depressed patients may experience a shift toward the manic phase; paranoid delusions, with or without associated hostility, may be exaggerated. In any of these circumstances, it may be advisable to reduce the dose of protriptyline HCl or to use a major tranquilizing drug concurrently. Symptoms, such as anxiety or agitation, may be aggravated in overactive or agitated patients.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. May enhance response to alcohol and effects of barbiturates and other CNS depressants. Possibility of suicide in depressed patients remains during treatment and until significant remission occurs; this type of patient should not have access to large quantities of the drug. Concurrent administration with electroshock therapy may increase hazards of therapy; such treatment should be limited to patients for whom it is essential. Discontinue drug several days before elective surgery, if possible. Both elevation and lowering of blood sugar levels have been reported.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions which have not been reported with this specific drug. However, the pharmacologic similarities among the tricyclic antidepressant drugs require that each of the reactions be considered when protriptyline HCl is administered. Protriptyline HCl is more likely to aggravate agitation and anxiety and produce cardiovascular reactions such as tachycardia and hypotension.

Cardiovascular: hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke.

Psychiatric: confusional states (especially in the elderly) with hallucinations, disorientation, delusions, anxiety, restlessness, agitation; insomnia, panic, and nightmares; hypomania; exacerbation of psychosis.

Neurological: numbness, tingling, and paresthesias of extremities; incoordination, ataxia, tremors, peripheral neuropathy; extrapyramidal symptoms; seizures; alteration in EEG patterns, tinnitus.

Anticholinergic: dry mouth and rarely associated sublingual adenitis; blurred vision, disturbance of accommodation, mydriasis; constipation, paralytic ileus; urinary retention, delayed micturition, dilatation of the urinary tract.

Allergic: skin rash, petechiae, urticaria, itching, photosensitization (avoid excessive exposure to sunlight), edema (general, or of face and tongue), drug fever.

Hematologic: bone marrow depression; agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia.

Gastrointestinal: nausea and vomiting, anorexia, epigastric distress, diarrhea, peculiar taste, stomatitis, abdominal cramps, black tongue.

Endocrine: gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido, impotence; testicular swelling; elevation or depression of blood sugar levels.

Other: jaundice (simulating obstructive); altered liver function; weight gain or loss; perspiration; flushing; urinary frequency, nocturia; drowsiness, dizziness, weakness and fatigue; headache; parotid swelling; alopecia.

Withdrawal Symptoms: though not indicative of addiction, abrupt cessation of treatment after prolonged therapy may produce nausea, headache, and malaise.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of other tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets, containing 5 mg and 10 mg protriptyline HCl each, in single-unit packages of 100 and bottles of 100 and 1000.

  By Ruth Moulton
- Michael Shepherd on Sir Aubrey Lewis

If you think adjunctive antianxiety therapy is indicated...

Consider Serax® (oxazepam). It has been proved useful when anxiety and tension aren't responsive to simple reassurance and counsel.

Serax has been found valuable, particularly in the older patient, in the management and control of clinically significant anxiety, tension, agitation and irritability. It may also be useful where anxiety accompanies an underlying organic disorder.

Of special importance to elderly patients, Serax may be taken generally without fear of serious side effects.* Its dosage flexibility† generally permits adjustment to individual patient needs, making Serax a convenient adjunct to your therapy in the older patient.

Special care must, of course, be taken in prescribing antianxiety agents for elderly patients, especially where cardiac complications might ensue from a drop in blood pressure. And careful attention must be paid to dosage recommendations and follow-up observation.

See following important information.
See package circular for full prescribing information.

In Brief:

Indications: Oxazepam is indicated for the management and control of anxiety, tension, agitation, irritability and related symptoms. Such symptoms are commonly seen in patients with a diagnosis of psychoneurotic reaction, psychophysiological reaction, personality disorder, or in patients with underlying organic disease. Anxiety associated with depression is also responsive to oxazepam therapy. This product has been found particularly useful in the management of anxiety, tension, agitation and irritability in older patients. Alcoholics with acute tremulousness, inebriation or with anxiety associated with alcohol withdrawal are responsive to therapy.

Contraindications: History of previous hypersensitivity to oxazepam. Oxazepam is not indicated in psychoses.

Warning: Use in Pregnancy:

An increased risk of congenital malformations associated with the use of minor tranquilizers (chlordiazepoxide, diazepam, and meprobamate) during the first trimester of pregnancy has been suggested in several studies. Serax, a benzodiazepine derivative, has not been studied adequately to determine whether it, too, may be associated with an increased risk of fetal abnormality. Because use of these drugs is rarely a matter of urgency, their use during this period should almost always be avoided. The possibility that a woman of childbearing potential may be pregnant at the time of institution of therapy should be considered. Patients should be advised that if they become pregnant during therapy or intend to become pregnant they should communicate with their physician about the desirability of discontinuing the drug.

Precautions: Hypotensive reactions are rare, but use with caution where cardiac complications could ensue from a fall in blood pressure, especially in the elderly. Withdrawal symptoms upon discontinuation have been noted in some patients exhibiting drug dependence through chronic overdose. Carefully supervise dose and amounts prescribed, especially for patients prone to self-overdose; excessive, prolonged use in susceptible patients (alcoholics, ex-addicts, etc.) may result in dependence or habituation. Reduce dosage gradually after prolonged excessive dosage to avoid possible epileptiform seizures. Withdrawal symptoms following abrupt discontinuance are similar to those seen with barbiturates. Caution patients against driving or operating machinery until absence of drowsiness or dizziness is ascertained. Warn patients of possible reduction in alcohol tolerance. Not indicated in children under 6 years; absolute dosage for 6- to 12-year-olds not established.

Adverse Reactions: Therapy-interrupting side effects are rare. Transient mild drowsiness is common initially; if persistent, reduce dosage. Dizziness, vertigo and headache have also occurred infrequently; syncope, rarely. Mild paradoxical reactions (excitement, stimulation of affect) are reported in psychiatric patients. Minor diffuse rashes (morbilliform, urticarial and maculopapular) are rare. Nausea, lethargy, edema, slurred speech, tremor and altered libido are rare and generally controllable by dosage reduction. Although rare, leukopenia and hepatic dysfunction including jaundice have been reported during therapy. Periodic blood counts and liver function tests are advised. Ataxia, reported rarely, does not appear related to dose or age. These side reactions, noted with related compounds, are not yet reported: paradoxical excitation with severe rage reactions, hallucinations, menstrual irregularities, change in EEG pattern, blood dyscrasias (including agranulocytosis), blurred vision, diplopia, incontinence, stupor, disorientation, fever and euphoria.

Availability: Capsules of 10, 15 and 30 mg. oxazepam; tablets of 15 mg. oxazepam.

In clinically significant anxiety

Tested by time and experience i

1962

"...a considerable decrease of hyperactivity...."[1]
Knobel, 1962

Over a decade of controlled studies and clinical experience has shown the effectiveness of Ritalin in reducing the hyperactivity,[1-3] distractibility,[1,4,5] and disorganized behavior[1-8] in the MBD child.

By lessening the effects of motor and attentional disorders, Ritalin can help the MBD child to better focus his attention on meaningful stimuli and thus can often improve cognition and promote learning.[6,9]

And side effects – insomnia a appetite loss – with Ritalin have occurred less frequently than with dextroamphetamine.[10,11]

Indeed, Ritalin is currently a drug of choice in many MBD situations,[10,12] and can prove to be an important element in many complete remedial programs for MBD.

Therapy with Ritalin should b undertaken only after a medical diagnosis of MBD has been made. Drug treatment is not indicated fo all children with MBD.

Dosage should be periodically interrupted. Often, these interruptions reveal some "stabilization" in the child's behavior even without medication, permitting a reduction in dosage and eventual discontinuance of drug therapy.

TABLETS

INDICATION

Minimal Brain Dysfunction in Children—as adjunctive therapy to other remedial measures (psychological, educational, social)

Special Diagnostic Considerations

Specific etiology of Minimal Brain Dysfunction (MBD) is unknown, and there is no single diagnostic test. Adequate diagnosis requires the use not only of medical but of special psychological, educational, and social resources. Characteristics commonly reported include: chronic history of short attention span, distractibility, emotional lability, impulsivity, and moderate to severe hyperactivity; minor neurological signs and abnormal EEG. Learning may or may not be impaired. The diagnosis of MBD must be based upon a complete history and evaluation of the child and not solely on the presence of one or more of these characteristics.

Drug treatment is not indicated for all children with MBD. Stimulants are not intended for use in the child who exhibits symptoms secondary to environmental factors and/or primary psychiatric disorders, including psychosis. Appropriate educational placement is essential and psychosocial intervention is generally necessary. When remedial measures alone are insufficient, the decision to prescribe stimulant medication will depend upon the physician's assessment of the chronicity and severity of the child's symptoms.

CONTRAINDICATIONS

Marked anxiety, tension, and agitation, since Ritalin may aggravate these symptoms. Also contraindicated in patients known to be hypersensitive to the drug and in patients with glaucoma.

WARNINGS

Ritalin should not be used in children under six years, since safety and efficacy in this age group have not been established.

Sufficient data on safety and efficacy of long-term use of Ritalin in children with minimal brain dysfunction are not yet available.

Although a causal relationship has not been established, suppression of growth (*ie*, weight gain and/or height) has been reported with long-term use of stimulants in children. Therefore, children requiring long-term therapy should be carefully monitored.

Ritalin should not be used for severe depression of either exogenous or endogenous origin or for the prevention of normal fatigue states.

Ritalin may lower the convulsive threshold in patients with or without prior seizures; with or without prior EEG abnormalities, even in absence of seizures. Safe concomitant use of anticonvulsants and Ritalin has not been established. If seizures occur, Ritalin should be discontinued.

Use cautiously in patients with hypertension. Blood pressure should be monitored at appropriate intervals in all patients taking Ritalin, especially those with hypertension.

Symptoms of visual disturbances have been encountered in rare cases. Difficulties with accommodation and blurring of vision have been reported.

Drug Interactions

Ritalin may decrease the hypotensive effect of guanethidine. Use cautiously with pressor agents and MAO inhibitors. Ritalin may inhibit the metabolism of coumarin anticoagulants, anticonvulsants (phenobarbital, diphenylhydantoin, primidone), phenylbutazone, and tricyclic antidepressants (imipramine, desipramine). Downward dosage adjustments of these drugs may be required when given concomitantly with Ritalin.

Usage in Pregnancy

Adequate animal reproduction studies to establish safe use of Ritalin during pregnancy have not been conducted. Therefore, until more information is available, Ritalin should not be prescribed for women of childbearing age unless, in the opinion of the physician, the potential benefits outweigh the possible risks.

Drug Dependence

Ritalin should be given cautiously to emotionally unstable patients, such as those with a history of drug dependence or alcoholism, because such patients may increase dosage on their own initiative. Chronically abusive use can lead to marked tolerance and psychic dependence with varying degrees of abnormal behavior. Frank psychotic episodes can occur, especially with parenteral abuse. Careful supervision is required during drug withdrawal, since severe depression as well as the effects of chronic overactivity can be unmasked. Long-term follow-up may be required because of the patient's basic personality disturbances.

PRECAUTIONS

Patients with an element of agitation may react adversely; discontinue therapy if necessary.

Periodic CBC, differential, and platelet counts are advised during prolonged therapy.

ADVERSE REACTIONS

Nervousness and insomnia are the most common adverse reactions but are usually controlled by reducing dosage and omitting the drug in the afternoon or evening. Other reactions include: hypersensitivity (including skin rash, urticaria, fever, arthralgia, exfoliative dermatitis, erythema multiforme with histopathological findings of necrotizing vasculitis, and thrombocytopenic purpura); anorexia; nausea; dizziness; palpitations; headache; dyskinesia; drowsiness; blood pressure and pulse changes, both up and down; tachycardia; angina; cardiac arrhythmia; abdominal pain; weight loss during prolonged therapy. Toxic psychosis has been reported. Although a definite causal relationship has not been established, the following have been reported in patients taking this drug: leukopenia and/or anemia; a few instances of scalp hair loss.

In children, loss of appetite, abdominal pain, weight loss during prolonged therapy, insomnia, and tachycardia may occur more frequently; however, any of the other adverse reactions listed above may also occur.

DOSAGE AND ADMINISTRATION

Children with Minimal Brain Dysfunction (6 years and over)

Start with small doses (*eg*, 5 mg before breakfast and lunch) with gradual increments of 5 to 10 mg weekly. Daily dosage above 60 mg is not recommended. If improvement is not observed after appropriate dosage adjustment over a one-month period, the drug should be discontinued.

If paradoxical aggravation of symptoms or other adverse effects occur, reduce dosage, if necessary, discontinue the drug.

Ritalin should be periodically discontinued t assess the child's condition. Improvement r be sustained when the drug is either tempo-rarily or permanently discontinued.

Drug treatment should not and need not be indefinite and usually may be discontinued after puberty.

HOW SUPPLIED

Tablets, 20 mg (peach, scored); bottles of 1(and 1000.

Tablets, 10 mg (pale green, scored); bottles 100, 500, 1000 and Accu-Pak® blister units 100.

Tablets, 5 mg (pale yellow); bottles of 100, 5 and 1000.

Consult complete product literature before prescribing.

DELINQUENCY AND PSYCHOPATHOLOGY

by DOROTHY OTNOW LEWIS, M.D. and DAVID BALLA, Ph.D.

The book explores recent developments in the knowledge of the genesis and nature of certain psychiatric disorders, particularly schizophrenia and central nervous system dysfunction, and brings this knowledge to bear on the understanding psychotic and organic symptomatology in some delinquent children and serious psychopathology in some of their parents and calls attention to the many different manifestations disturbed thinking can take. Perhaps of greatest importance, the book stresses the time and expertise needed to bring to light certain serious psychiatric disorders underlying a wide variety of delinquent behaviors.

CONTENTS: Foreword *by Dennis P. Cantwell, M.D.* Foreword *by the Honorable Justine Wise Polier.* Introduction. Psychiatric and Sociological Viewpoints: *Changing Perspectives and Emphases.* Diagnostic Evaluation. Sociopathy and Its Synonyms: *Diagnosis of Questionable Usefulness.* The Children: *Central Nervous System Dysfunction, A Variety of Clinical Pictures.* Psychomotor Epileptic Symptomatology, Paranoid Ideation, and Delinquent Behaviors: *A Triad.* Psychotic Symptomatology: *Clinical Observations.* Epidemiological Correlates of Clinical Observations in Children. The Parents: *Clinical and Epidemiological Findings.* Parental Schizophrenia and Delinquency: *An Epidemiological Study.* Reflections: *Implications for Ongoing Work.*

The TRIAVIL® Potential in the management of moderate to severe anxiety with depression

When time and talk are not enough...
The therapist is the primary catalyst for change in the psychotherapeutic relationship. However, when patients suffer from moderate to severe anxiety with depression, there are situations when TRIAVIL can often be a useful adjunct.

...TRIAVIL may help
There are three important benefits you may expect when TRIAVIL is part of the treatment program: (1) When symptoms of moderate to severe anxiety or agitation with depression are relieved, the patient may become more accessible and cooperative. (2) As somatic manifestations are controlled, attention may be focused on underlying causative factors. (3) Symptomatic relief may enable the patient to function more effectively in his daily life while your work with the patient progresses.

Tablets TRIAVIL are available in four different combinations affording flexibility and individualized dosage adjustment. Since it is simpler to remember to take one tablet rather than several (particularly in multiple daily doses), your patients on TRIAVIL will be more likely to take proper doses of the medication.

TRIAVIL is contraindicated in CNS depression from drugs; in the presence of evidence of bone marrow depression; and in patients hypersensitive to phenothiazines or amitriptyline. It should not be used during the acute recovery phase following myocardial infarction or in patients who have received an MAOI within two weeks. Patients with cardiovascular disorders should be watched closely. Not recommended in children or during pregnancy. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. Antiemetic effect may obscure toxicity due to other drugs or mask other disorders. Since suicide is a possibility in any depressive illness, patients should not have access to large quantities of the drug. Hospitalize as soon as possible any patient suspected of having taken an overdose.

MSD

For a brief summary of prescribing information, please turn to the following page.

LIBRARY

when patients exhibit moderate to marked anxiety or agitation with symptoms of depression

TRIAVIL® **containing perphenazine and amitriptyline HCl**

a tranquilizer-antidepressant

for highly effective relief of depression with moderate anxiety

TRIAVIL®

containing perphenazine and amitriptyline HCl a tranquilizer-antidepressant

Available:

TRIAVIL® 2-25: Each tablet contains 2 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 2-10: Each tablet contains 2 mg perphenazine and 10 mg amitriptyline HCl

TRIAVIL® 4-25: Each tablet contains 4 mg perphenazine and 25 mg amitriptyline HCl

TRIAVIL® 4-10: Each tablet contains 4 mg perphenazine and 10 mg amitriptyline HCl

INITIAL THERAPY FOR MANY PATIENTS
TRIAVIL® 2-25 (or TRIAVIL® 4-25) t.i.d. or q.i.d.

FOR FLEXIBILITY IN ADJUSTING MAINTENANCE THERAPY
TRIAVIL® 2-10 (or TRIAVIL® 4-10)

CONTRAINDICATIONS: Central nervous system depression from drugs (barbiturates, alcohol, narcotics, analgesics, antihistamines); bone marrow depression; known hypersensitivity to phenothiazines or amitriptyline. Do not give concomitantly with MAOI drugs because hyperpyretic crises, severe convulsions, and deaths have occurred from such combinations. Allow minimum of 14 days between therapies, then initiate therapy with TRIAVIL cautiously, with gradual increase in dosage until optimum response is achieved. Not recommended for use during acute recovery phase following myocardial infarction.

WARNINGS: TRIAVIL should not be given with guanethidine or similarly acting compounds. Use cautiously in patients with history of urinary retention, angle-closure glaucoma, increased intraocular pressure, or convulsive disorders. In patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely. Tricyclic antidepressants, including amitriptyline HCl, particularly in high doses, have been reported to produce arrhythmias, sinus tachycardia, and prolongation of conduction time. Myocardial infarction and stroke have been reported with tricyclic antidepressant drugs. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. Caution patients performing hazardous tasks, such as operating machinery or driving motor vehicles, that drug may impair mental and/or physical abilities. Not recommended in children or during pregnancy.

PRECAUTIONS: Suicide is a possibility in depressed patients and may remain until significant remission occurs. Such patients should not have access to large quantities of this drug.

Perphenazine: Should not be used indiscriminately. Use with caution in patients who have previously exhibited severe adverse reactions to other phenothiazines. Likelihood of untoward actions is greater with high doses. Closely supervise with any dosage. The antiemetic effect of perphenazine may obscure signs of toxicity due to overdosage of other drugs or make more difficult the diagnosis of disorders such as brain tumor or intestinal obstruction. A significant, not otherwise explained, rise in body temperature may suggest individual intolerance to perphenazine, in which case discontinue.

If hypotension develops, epinephrine should not be employed, as its action is blocked and partially reversed by perphenazine. Phenothiazines may potentiate the action of central nervous system depressants (opiates, analgesics, antihistamines, barbiturates, alcohol) and atropine. In concurrent therapy with any of these, TRIAVIL should be given in reduced dosage. May also potentiate the action of heat and phosphorous insecticides.

Amitriptyline: In manic-depressive psychosis, depressed patients may experience a shift toward the manic phase if they are treated with an antidepressant. Patients with paranoid symptomatology may have an exaggeration of such symptoms. The tranquilizing effect of TRIAVIL seems to reduce the likelihood of this effect. When amitriptyline HCl is given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required. Paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs.

Caution is advised if patients receive large doses of ethchlorvynol concurrently. Transient delirium has been reported in patients who were treated with 1 g of ethchlorvynol and 75-150 mg of amitriptyline HCl.

Amitriptyline HCl may enhance the response to alcohol and the effects of barbiturates and other CNS depressants.

Concurrent administration of amitriptyline HCl and electroshock therapy may increase the hazards associated with such therapy. Such treatment should be limited to patients for whom it is essential. Discontinue several days before elective surgery if possible. Elevation and lowering of blood sugar levels have both been reported. Use, with caution in patients with impaired liver function.

ADVERSE REACTIONS: Similar to those reported with either constituent alone.

Perphenazine: Side effects may be any of those reported with phenothiazine drugs: extrapyramidal symptoms (opisthotonus, oculogyric crisis, hyperreflexia, dystonia, akathisia, acute dyskinesia, ataxia, parkinsonism) can usually be controlled by the concomitant use of effective antiparkinsonian drugs and/or by reduction in dosage, but sometimes persist after discontinuation of the phenothiazine.

Tardive dyskinesia may appear in some patients on long-term therapy or may occur after drug therapy with phenothiazines and related agents has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. Symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Involuntary movements of the extremities sometimes occur. There is no known treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms. It is advised that all antipsychotic agents be discontinued if the above symptoms appear. If treatment is reinstituted, or dosage of the particular drug increased, or another drug substituted, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome, and that the full-blown syndrome may not develop if medication is stopped when lingual vermiculation appears.

Other side effects are skin disorders (photosensitivity, itching, erythema, urticaria, eczema, up to exfoliative dermatitis); other allergic reactions (asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions); peripheral edema; reversed epinephrine effect; hyperglycemia; endocrine disturbances (lactation, galactorrhea, gynecomastia, disturbances of menstrual cycle); altered cerebrospinal fluid proteins; paradoxical excitement; hypertension, hypotension, tachycardia, and ECG abnormalities (quinidine-like effect); reactivation of psychotic processes; catatonic-like states; autonomic reactions, such as dry mouth or salivation, headache, anorexia, nausea, vomiting, constipation, obstipation, urinary frequency or incontinence, blurred vision, nasal congestion, and a change in pulse rate; hypnotic effects; pigmentary retinopathy; corneal and lenticular pigmentation; occasional lassitude, muscle weakness, mild insomnia. Other adverse reactions reported with various phenothiazine compounds include blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, agranulocytosis, eosinophilia); liver damage (jaundice, biliary stasis); grand mal convulsions; cerebral edema; polyphagia; photophobia; skin pigmentation; and failure of ejaculation.

Amitriptyline: Note: Listing includes a few reactions not reported for this drug, but which have occurred with other pharmacologically similar tricyclic antidepressant drugs. *Cardiovascular:* Hypotension; hypertension; tachycardia; palpitation; myocardial infarction; arrhythmias; heart block; stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth; blurred vision; disturbance of accommodation; constipation; paralytic ileus; urinary retention; dilatation of urinary tract. *Allergic:* Skin rash; urticaria; photosensitization; edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis; leukopenia; eosinophilia; purpura; thrombocytopenia. *Gastrointestinal:* Nausea; epigastric distress; vomiting; anorexia; stomatitis; peculiar taste; diarrhea; parotid swelling; black tongue. Rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male; breast enlargement and galactorrhea in the female; increased or decreased libido; elevated or lowered blood sugar levels. *Other:* Dizziness; weakness; fatigue; headache; weight gain or loss; increased perspiration; urinary frequency; mydriasis; drowsiness; alopecia. *Withdrawal Symptoms:* Abrupt cessation after prolonged administration may produce nausea, headache, and malaise. These are not indicative of addiction.

OVERDOSAGE: All patients suspected of having taken an overdosage should be admitted to a hospital as soon as possible. Treatment is symptomatic and supportive. However, the intravenous administration of 1–3 mg of physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage of physostigmine should be repeated as required particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine. On this basis, in severe overdosage with perphenazine-amitriptyline combinations, symptomatic treatment of central anticholinergic effects with physostigmine salicylate should be considered.

FIFTH INTERNATIONAL GENDER DYSPHORIA SYMPOSIUM

The Eastern Virginia Inter-Hospital Medical Education Committee will sponsor the Fifth International Gender Dysphoria Symposium in Norfolk, Virginia, February 10-13, 1977. Presentations will be made in the areas of "Psychiatric Aspects of the Gender Dysphoria Syndrome," "Considerations of Male to Female and Female to Male Transsexuals," "Diagnostic Dilemmas and Treatment Failures" and "Follow-Up Studies." Additionally, guest speakers will address such topics as Therapeutic Guidelines, Legal Problems, Nursing Aspects and Theoretical Aspects of the Gender Dysphoria Syndrome. This continuing medical education program will be accredited by the American Medical Association and the associations of the various disciplines involved. All professionals are invited to attend. For registration information contact: Terry Salasky-Coordinator, Gender Dysphoria Symposium, P.O. Box 1980, Norfolk, Virginia 23501.

2-mg, 5-mg, 10-mg scored tablets

Initial calming in hours.

Your anxious psychoneurotic patient will find the prompt action of Valium highly reassuring. It's immediate, tangible proof that his medication is working.

Significant improvement in days.

As Valium reduces overwhelming symptoms of anxiety and psychic tension, your patient begins to feel better often within a few days.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; symptomatic relief of acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology; spasticity caused by upper motor neuron disorders; athetosis; stiff-man syndrome; convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma; may be used in patients with open angle glaucoma who are receiving appropriate therapy.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms (similar to those with barbiturates and alcohol) have occurred following abrupt discontinuance (convulsions, tremor, abdominal and muscle cramps, vomiting and sweating). Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence.

Usage in Pregnancy: **Use of minor tranquilizers during first trimester should almost always be avoided because of increased risk of congenital malformations as suggested in several studies. Consider possibility of pregnancy when instituting therapy; advise patients to discuss therapy if they intend to or do become pregnant.**

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed; drugs such as phenothiazines, narcotics, barbiturates, MAO inhibitors and other antidepressants may potentiate its action. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

Dosage: Individualize for maximum beneficial effect. *Adults:* Tension, anxiety and psychoneurotic states, 2 to 10 mg b.i.d. to q.i.d.; alcoholism, 10 mg t.i.d. or q.i.d. in first 24 hours, then 5 mg t.i.d. or q.i.d. as needed; adjunctively in skeletal muscle spasm, 2 to 10 mg t.i.d. or q.i.d.; adjunctively in convulsive disorders, 2 to 10 mg b.i.d. to q.i.d. *Geriatric or debilitated patients:* 2 to 2½ mg, 1 or 2 times daily initially, increasing as needed and tolerated. (See Precautions.) *Children:* 1 to 2½ mg t.i.d. or q.i.d. initially, increasing as needed and tolerated (not for use under 6 months).

Supplied: Valium®(diazepam) Tablets, 2 mg, 5 mg and 10 mg—bottles of 100 and 500; Tel-E-Dose®packages of 100, available in trays of 4 reverse-numbered boxes of 25, and in boxes containing 10 strips of 10; Prescription Paks of 50, available singly and in trays of 10.

ACUTE DRUG ABUSE EMERGENCIES

A Treatment Manual

edited by PETER G. BOURNE

This volume represents a collection of the preferred methods for treating all of the major drug abuse emergencies that a physician or other health professional is likely to encounter. Each author was asked to describe in simple, brief, and easy-to-follow steps the manner in which he personally treats these emergencies. This volume is intended as a ready resource for the physician who is confronted with an acute drug abuse emergency, so that he can rapidly ascertain the most effective and appropriate treatment. In particular it is intended to be a simple guide for the physician who is not involved regularly in the treatment of drug abuse problems but who, when confronted by them, needs to know quickly the best way to handle them.

SECTION HEADINGS: Differential Diagnosis. Emergency Treatment of Opiate Overdoses. Emergency Treatment of Adverse Reactions to CNS Stimulants. Emergency Treatment of Adverse Reactions to Hallucinogenic Drugs. Emergency Treatment of Acute Reactions to Cannabis Derivatives. Emergency Treatment of Inhalation Psychosis and Related States. Emergency Treatment of Acute Alcohol Intoxication. Special Problems.

The vulnerable ages

The first epileptic seizure is most likely to occur during early childhood and at the onset of puberty

About 9 out of 10 epileptics experience their first seizure before the age of 20—with the highest incidence between 5 and 7, when children start school, and at the onset of puberty, a time of physiological and psychic turmoil.[1] The most common type, grand mal, occurs in approximately 75% of epileptic children,[1] and more than 50% of patients who suffer initially from petit mal develop grand mal seizures before they reach the age of 16.[2]

Mysoline (primidone) for control of grand mal, psychomotor and focal epilepsy

At the onset and afterwards — used alone or as concomitant therapy, MYSOLINE may reduce the frequency and severity of major motor seizures—or even eliminate them. *Excellent* for control of grand mal. Valuable for control of psychomotor[1,3,4] and focal epilepsy as well.[5]

Add Mysoline when control with other anticonvulsants is inadequate — As concomitant therapy, MYSOLINE can improve seizure control in grand mal and psychomotor epilepsy. The combined use of phenobarbital, diphenylhydantoin, and MYSOLINE may have additive anticonvulsant effects without additive side effects.[6]

Change to Mysoline when other anticonvulsants fail — A changeover to MYSOLINE is frequently warranted when other anticonvulsants must be discontinued because of important side effects, or when grand mal seizures are refractory to phenobarbital, with or without diphenylhydantoin.[7]

Mysoline® (primidone)

may be the start of a better life for the epileptic

initial and maintenance therapy for
grand mal, psychomotor and focal epilepsy

BRIEF SUMMARY
(For full prescribing information, see package circular.)

MYSOLINE® Brand of PRIMIDONE

Anticonvulsant

ACTIONS: MYSOLINE acts on the central nervous system to raise seizure threshold or alter seizure pattern. The mechanism(s) of action of anticonvulsant drugs is not known.

Primidone has anticonvulsant activity *per se*. In addition, its two metabolites possess anticonvulsant qualities. The major metabolite is phenylethylmalonamide (PEMA); the other is phenobarbital. In addition to its own anticonvulsant potential, PEMA potentiates phenobarbital.

INDICATIONS: MYSOLINE, either alone or used concomitantly with other anticonvulsants, is indicated in the control of grand mal, psychomotor, and focal epileptic seizures. It may control grand mal seizures refractory to other anticonvulsant therapy.

CONTRAINDICATIONS: Primidone is contraindicated in: 1) patients with porphyria and 2) patients who are hypersensitive to phenobarbital (see ACTIONS).

WARNINGS: The abrupt withdrawal of antiepileptic medication may precipitate status epilepticus.

The therapeutic efficacy of a dosage regimen takes several days before it can be assessed.

Use in pregnancy: Recent reports strongly suggest an association between the use of anticonvulsant drugs by women with epilepsy and an elevated incidence of birth defects in children born to these women. Reference has been made to primidone in several cases in which it was used *in combination* with other anticonvulsants; but its teratogenicity has not been conclusively demonstrated. The possibility exists that other factors, *e.g.*, genetic factors or the epileptic condition, may contribute to the higher incidence of birth defects. The data also indicate that the great majority of mothers receiving anticonvulsant medication deliver normal infants.

Anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and risk to both mother and the unborn child.

When the nature, frequency, and severity of the seizures do not pose a clear threat to the patient, good medical practice requires that the physician weigh the expected therapeutic benefit of anticonvulsant therapy against possible risk on an individual basis.

Neonatal hemorrhage, with a coagulation defect resembling vitamin K deficiency, has been described in newborns whose mothers were taking primidone and other anticonvulsants. Pregnant women under anticonvulsant therapy should receive prophylactic vitamin K_1 therapy for one month prior to, and during, delivery.

The physician should weigh all of the foregoing considerations when treating and counseling epileptic women of childbearing potential.

PRECAUTIONS: The total daily dosage should not exceed 2 Gm. Since MYSOLINE therapy generally extends over prolonged periods, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.

In nursing mothers: There is evidence that in mothers treated with primidone, the drug appears in the milk in substantial quantities. Since tests for the presence of primidone in biological fluids are too complex to be carried out in the average clinical laboratory, it is suggested that the presence of undue somnolence and drowsiness in nursing newborns of MYSOLINE-treated mothers be taken as an indication that nursing should be discontinued.

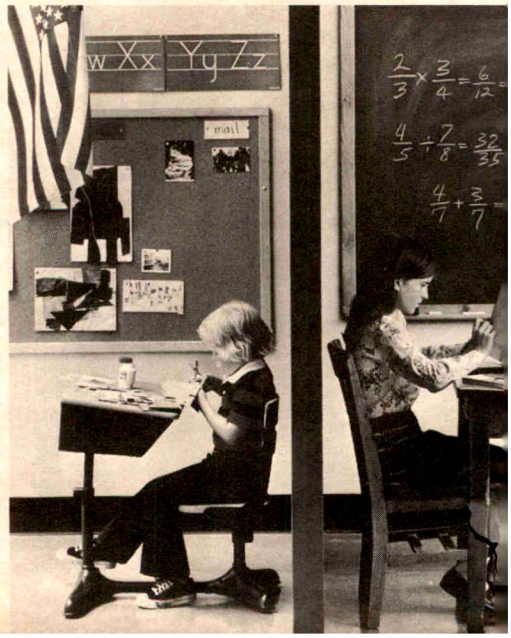
ADVERSE REACTIONS: The most frequently occurring early side effects are ataxia and vertigo. These tend to disappear with continued therapy, or with reduction of initial dosage. Occasionally, the following have been reported: nausea, anorexia, vomiting, fatigue, hyperirritability, emotional disturbances, sexual impotency, diplopia, nystagmus, drowsiness, and morbilliform skin eruptions. Occasionally, persistent or severe side effects may necessitate withdrawal of the drug. Megaloblastic anemia may occur as a rare idiosyncrasy to MYSOLINE and to other anticonvulsants. The anemia responds to folic acid, 15 mg. daily, without necessity of discontinuing medication.

DOSAGE AND ADMINISTRATION: The average adult dose is 0.75 to 1.5 Gm. per day. The initial dose is 250 mg. Increments of 250 mg. are added, usually at weekly intervals, to tolerance, or therapeutic effectiveness, up to daily doses not exceeding 2.0 Gm. A typical dosage schedule for the introduction of MYSOLINE (primidone) is as follows:

Adults and Children Over 8 Years of Age

1st Week 250 mg. daily at bedtime	*2nd Week* 250 mg. b.i.d.
3rd Week 250 mg. t.i.d.	*4th Week* 250 mg. q.i.d.

In children under 8 years of age, maintenance levels are established by a similar schedule, but at one-half the adult dosage. It is best to begin with 125 mg., with gradual weekly increases of 125 mg. a day, to a daily total usually between 500 mg. and 750 mg.



In patients already receiving other anticonvulsants: MYSOLINE should be gradually increased as dosage of the other drug(s) is maintained or gradually decreased. This regimen should be continued until satisfactory dosage level is achieved for combination, or the other medication is completely withdrawn. When therapy with this product alone is the objective, the transition should not be completed in less than two weeks.

MYSOLINE 50 mg. Tablet can be used to practical advantage when small fractional adjustments (upward or downward) may be required, as in the following circumstances:

- for initiation of combination therapy
- during "transfer" therapy
- for added protection in periods of stress or stressful situations that are likely to precipitate seizures (menstruation, allergic episodes, holidays, etc.)

HOW SUPPLIED: MYSOLINE *Tablets*—No. 430—Each tablet contains 250 mg. of primidone (scored), in bottles of 100 and 1,000. Also in unit dose package of 100. No. 431—Each tablet contains 50 mg. of primidone (scored), in bottles of 100 and 500. MYSOLINE *Suspension*—No. 3850—Each 5 cc. (teaspoonful) contains 250 mg. of primidone, in bottles of 8 fluid ounces.

In the hospitalized patient...

For Brief Summary, please see following page.

SANDOZ

SAN 6-640

ANTIPSYCHOTIC EFFICACY... INFREQUENT EXTRAPYRAMIDAL SYMPTOMS

Antipsychotic medication should not interfere with the patient's ability to participate in your total therapeutic program. That is why Mellaril (thioridazine) is an excellent choice. It is highly effective, and although extrapyramidal symptoms are characteristic of this class of drug, with Mellaril (thioridazine) extrapyramidal stimulation—notably pseudoparkinsonism—is infrequent. Adding an antiparkinsonian agent—which can cause its own side effects—can usually be avoided.

Mellaril (thioridazine) is not habituating and usually does not cause euphoria or undue sedation. (But, warn patients about undertaking activities requiring complete mental alertness.) And Mellaril (thioridazine) is contraindicated in patients with severe hypotensive or hypertensive heart disease.

MELLARIL® (THIORIDAZINE)

TABLETS: 50 mg, 100 mg, 150 mg, and 200 mg thioridazine HCl, U.S.P.

Before prescribing or administering, see Sandoz literature for full product information. The following is a brief summary.

Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.

Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides; carefully consider benefit versus risk in less severe disorders. During pregnancy, administer only when the potential benefits exceed the possible risks to mother and fetus.

Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy, observed primarily in patients receiving larger than recommended doses, is characterized by diminution of visual acuity, brownish coloring of vision, and impairment of night vision; the possibility of its occurrence may be reduced by remaining within recommended dosage limits. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving), and increase dosage gradually. Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension since phenothiazines may induce a reversed epinephrine effect on occasion. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.

Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; rarely, nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—ECG changes (see *Cardiovascular Effects* below). *Other*—Rare cases described as parotid swelling.

The following reactions have occurred with phenothiazines and should be considered: *Autonomic Reactions*—Miosis, obstipation, anorexia, paralytic ileus. *Cutaneous Reactions*—Erythema, exfoliative dermatitis, contact dermatitis. *Blood Dyscrasias*—Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. *Allergic Reactions*—Fever, laryngeal edema, angioneurotic edema, asthma. *Hepatotoxicity*—Jaundice, biliary stasis. *Cardiovascular Effects*—Changes in terminal portion of electrocardiogram, including prolongation of Q-T interval, lowering and inversion of T-wave, and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including Mellaril (thioridazine); these appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence of a causal relationship between these changes and significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms are not regarded as predictive. Hypotension, rarely resulting in cardiac arrest. *Extrapyramidal Symptoms*—Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonus, oculogyric crises, tremor, muscular rigidity, and akinesia. *Persistent Tardive Dyskinesia*—Persistent and sometimes irreversible tardive dyskinesia, characterized by rhythmical involuntary movements of the tongue, face, mouth, or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements) and sometimes of extremities may occur on long-term therapy or after discontinuation of therapy, the risk being greater in elderly patients on high-dose therapy, especially females; if symptoms appear, discontinue all antipsychotic agents. Syndrome may be masked if treatment is reinstituted, dosage is increased, or antipsychotic agent is switched. Fine vermicular movements of tongue may be an early sign, and syndrome may not develop if medication is stopped at that time. *Endocrine Disturbances*—Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. *Urinary Disturbances*—Retention, incontinence. *Others*—Hyperpyrexia; behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses, and toxic confusional states; following long-term treatment, a peculiar skin-eye syndrome marked by progressive pigmentation of skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea; systemic lupus erythematosus-like syndrome.

Child Custody Contests in Historical Perspective

BY ANDRE P. DERDEYN, M.D.

The author reviews the historical background of interparental child custody disputes. The father's superior right to custody in the nineteenth century continued the English common law tradition, but in the twentieth century the mother's claim became superior to the father's, reflecting women's generally increasing rights and the assumption that women are better suited to caring for children. Partly as a result of recent cultural changes leading to a beginning equalization of parental rights and partly because of greater concern for children, courts are starting to focus more on children's emotional needs. It is likely that courts will increasingly call on psychiatrists and other mental health professionals for help in making their decisions.

CONCERN FOR CHILDREN involved in interparental custody contests has recently been increasing. Efforts to change court practices to conform to the needs of children and to improve both the quantity and the quality of psychiatric consultation reflect this new interest.

Knowledge of the historical background of child custody contests affords some perspective on the current trends for change. This paper will touch briefly on practices in the older Western world and will treat in detail developments in the United States up to the present time.

PRACTICES IN THE OLDER WESTERN WORLD

Roman law gave the father absolute control over his children, whom he could sell or condemn to death with impunity (1). This concept of absolute right carried over into English law, where it prevailed until the fourteenth century without appreciable change (2). In the Middle Ages childhood was not seen as the unique phase of life we now consider it to be (3). It was customary to send children as young as 7 into service or apprenticeship, where learning was secondary to the labor a child performed for his or her master (4). The child and the servant appear to have been indistinguishable in terms of how they were treated; even the language often failed to use separate terms for each (3, p. 366). It was not until the sixteenth century that children began to be looked on as being of particular interest, having important and specific developmental tasks to perform, and being worthy of affection.

In eighteenth-century England the father's right to custody was almost without limit (5). Because the father owned or managed all of the family property, there was the practical consideration that, should the child be removed from the custody of the father, the financial support of the child was in question (6). However, the idea began to evolve that custody involved not only rights but also responsibilities for the care of the child. The English courts assumed jurisdiction over the welfare of children under the developing doctrine of parens patriae, which held that the Crown should protect all those who have no other protector (7). Percy Shelley in 1817 was one of the first men to lose custody of his children (8). Custody was refused because of his "vicious and immoral" atheistic beliefs.

The doctrine of parens patriae was given substance in 1839 in Talfourd's Act, which gave the court the power to determine custody of infants under the age of 7. The right of the mother to custody in England was gradually increased in a series of acts until the Guardianship of Infants Act of 1925 proclamed the equality of the mother and father with respect to the custody of their children (9). It was at about the same time that such equality was achieved in the United States.

Presented at the 129th annual meeting of the American Psychiatric Association, Miami Beach, Fla., May 10–14, 1976.

Dr. Derdeyn is Associate Professor of Psychiatry and Pediatrics and Training Director, Division of Child and Adolescent Psychiatry, University of Virginia Medical Center, Charlottesville, Va. 22901.

DEVELOPMENTS IN THE UNITED STATES TO THE MID-TWENTIETH CENTURY

The Father's Superior Right to Custody

In the United States child custody decisions reflected English common law in that they considered the father to have the superior right to custody. As in England, custody decisions took into account the fact that the father was vastly more competent financially than the mother. An 1826 text stated that "in consequence of the obligation of the father to provide for the maintenance of his infant children . . . he is entitled to the custody of their persons, and to the value of their labor and services" (10, pp. 162–163). An 1824 Rhode Island decision explained that the father's right to custody "is not on account of any absolute right of the father, but for the benefit of the infant, the law presuming it to be for his interest to be under the nurture and care of his natural protector, both for maintenance and education" (11, p. 31).

The right of the father remained superior to that of the mother throughout the last century. An 1842 New York decision stated, "The question then is, which of these parties, the father or the mother, has the best title to the custody of the child? The opinion of this court has been repeatedly expressed that by the law of the land the claims of the father are superior to those of the mother" (12, p. 659). In 1857 a New York judge wrote that a husband with regard to his wife was "wanting in respectful and kind attention to her, and has often used harsh, profane and vituperative expressions to her, and to others concerning her, but he has been guilty of no such misconduct as would justify the wife in a separation" (13, p. 522). The judge added,

> The only difficulty, if any, in the present case, in regard to the right of the father to retain the child, arises from the child being of tender age, and deriving its sustenance, in part, from the breasts of the mother. But upon the evidence, I think these circumstances form no obstacle to the father's right. (13, p. 523)

Custody was thereupon awarded to the father. An 1860 New Hampshire opinion started with,

> It is a well-settled doctrine of the common law, that the father is entitled to the custody of his minor children, as against the mother and everybody else; that he is bound for their maintenance and nurture, and has the corresponding right to their obedience and their services. (14, p. 273)

In a similar vein, it was stated in an 1878 Virginia decision that "the father is the legal custodian of the minor children, and they will not be taken from his custody without the strongest reasons therefore" (15). In that case a wife who refused to live with her husband was denied a divorce and also denied not only custody but visitation with the couple's 4-year-old boy.

An 1881 Arkansas case held,

> It is one of the cardinal principles of nature and of law that, as against strangers, the father, however poor and humble, if able to support the child in his own life style, and of good moral character, cannot, without the most shocking injustice, be deprived of the privilege by anyone whatever, however brilliant the advantage he may offer. It is not enough to consider the interests of the child alone. (16, p. 28)

A consideration of child support at the end of the nineteenth century reflects the financial basis of the father's primary right to custody as well as the relative unimportance of the child's welfare. The historical view of children as essentially the property of the father continued to be influential. An 1891 law text explained the linkage of support with the father's primary right to custody: "As the first duty to support the child rests on the father, he is *prima facie* and before all others . . . entitled to the custody" (17, p. 453). This principle was followed to its logical extreme in some courts, which absolved a father deprived of custody of the duty to support his child. An 1883 Massachusetts case held that "a father is not liable for the support of his minor child, after the custody of the child has been given to the mother by a decree of this court" (18, p. 187). In 1895 a Maine court addressed the same issue, stating,

> When a divorce is granted to a wife, and as a consequence of it she has committed to her the care and custody of her minor child, it follows that the father becomes entirely absolved from the common law obligation which previously rested upon him to support such child. (19, p. 796)

These were by no means idiosyncratic opinions. An 1881 text reads,

> It seems to be a principle of the unwritten law, that the right to the services of the child and the obligation to maintain them go together. The consequence of which would be, that, if the assignment of the custody to the mother extends to divesting the father of his title to the services of the children, he cannot be compelled to maintain them otherwise than in pursuance of some statutory regulation. (20, p. 473)

The concept that a father has some responsibility to children not in his custody developed in statutes and in case law in the early 1900s (21, 22). Up to the present time the courts have quite consistently held to the responsibility of the father to support, regardless of whether or not he has custody. Therefore, an important financial constraint against awarding custody to the mother was removed in the early part of the twentieth century (23).

The Changing Status of Women

Many social changes began to impinge importantly on the issue of custody. By the middle of the nineteenth century the United States was beginning to change from a primarily agricultural, rural society to an industrialized, urban one. There were a number of

indications of important changes in women's place in society: women began to vote, to own property in their own right, and to be gainfully employed in greater numbers. At the same time, the country's new interest in children began to be manifested by the development of public education, children's aid societies (24), and child labor laws (25). Not only did women start to develop more rights and more economic competence, but society, influenced by early interest in child development, stressed the importance of maternal care.

The mother's right to custody was first asserted with regard to young children. As early as 1813, a mother had won custody of daughters 7 and 10 years of age (26). However, the husband, who had previously deserted the family, regained the custody of his daughters 2½ years later (27). An 1840 decision stated the view prevailing at that time:

> The doctrine of the common law has not been overthrown, although it has been weakened in the United States; that still upon a question of guardianship, with the exception of very tender infancy, a positive unfitness in the father must be shown before children can be withheld or withdrawn from his charge. (28, p. 501)

The period during which maternal care was necessary was seen as a short one. A 23-month-old girl was awarded to her mother in 1840 (29) and returned to her father when she was 4 years, 6 months old, on the ground that the child could then be delivered to the father without injury (12). Similarly, in Virginia in 1872 a 3-year-old girl was awarded to her mother, but at age 4 she was given to the custody of her father. The court wrote, "The tender nursing period has passed by, and the time for moral training and impressions has arrived" (30, p. 174).

The mother's right to custody on the basis of the tender years presumption grew rapidly in strength. Late in the nineteenth century a legal writer, after acknowledging the father's paramount right, went on to say,

> There may be cases in which the court, from a consideration of the child's welfare, would not award its custody to the father, even though no fault or neglect of duty could be imputed to him. A child of very tender years needs the care and attention of a mother, . . . at least until it has reached an age when the father can properly care for it. It can only be in such cases as this, where the child, from its extreme youth or sickness, needs a mother's care, that the court can deprive the father of the right to the child's custody, where the father can properly care for the child, and is in every way a fit person to have the charge of it, and has not in any way neglected the child or relinquished his rights. (31, pp. 250–251)

By 1880 a court that awarded a 4½-year-old boy to his mother was able to state the tender years presumption in a more positive fashion: "The claim of a mother during the early years of an infant's life to the care of her child is to be preferred to that of the father" (32, p. 357). The view of most other courts, however, was that the mother's right to custody of a young child was a temporary exemption to the proper scheme of things. As late as 1905, a court that had awarded a 3-year-old boy to his mother because of his young age held 2 years later that "the father, by reason of his paramount right in law, is entitled to the custody of the child" (33, p. 862).

The tender years presumption was one of the first tangible legal issues on which the developing rights of the mother were based. The best interests of the child was the other.

At the turn of the century, when women were gaining new rights and children were generally being accorded more attention, some of the change in the law regarding custody of children was crystallized in the best interests of the child test. Two decisions are credited with its origin. In *Chapsky v. Wood* (34) in 1881 a psychologically astute judge ordered that a 5-year-old girl remain with the maternal grandmother by whom she had been raised rather than being placed in the custody of her father. The judge wrote that the father had the natural right to custody but that the paramount consideration was the welfare of the child. In the second case, *Finlay v. Finlay* (35) in 1925, the judge wrote that in custody cases the judge "does not proceed upon the theory that the petitioner, whether father or mother, has a cause for action against the other or indeed against anyone. He acts as *parens patriae* to do what is best for the interests of the child" (35, p. 626).

The best interests of the child test, although it did signal an enhanced consideration of the child's needs, had more significance in that it reflected the strengthening of the mother's right to custody. When the best interests test came into use in the early years of the twentieth century, the courts were well along in the process of giving the mother the advantage in custody decisions. The best interests test is not a test at all; it is a general principle, expressed in practically every custody decision, and it gives no indication of the degree of attention paid to the child's needs. One article on the child's right to counsel noted,

> The "best interest of the child" is often established by showing the unfitness of a particular parent. The conclusion which follows is that it would not be in the best interests of the child to award custody to that parent. The decision is reached by a process of elimination and justified by a euphemism. (36, p. 111)

Although of questionable value, the best interests test appears in the statutes of 48 states (37). The best interests of the child test has throughout most of its existence primarily supported the mother's claim.

The Mother's Superior Right to Custody

The father's advantage in custody claims was gradually eroded. A 1921 text noted that the courts had considerably modified the idea of the father's paramount right and had adopted "the equitable principle that this

right must yield to considerations affecting the well-being of the child" (38, p. 344). In 1926 a legal writer estimated that regarding the parents' relative entitlement to custody "the father had perhaps a slight advantage over the mother" (39, p. 326).

Soon the mother developed rights to custody far superior to those of the father. A number of factors enhanced the mother's right and ability to have custody of her children. In addition to women's generally increasing rights and economic capability, child support from former spouses became more consistently available. Whereas the father had been presumed to have the right to custody according to the English common law tradition and his greater earning capacity, the mother's right to custody was a moral one based on a developing cultural assumption that the woman was better suited to caring for children (40).

The emphasis on the benefits of mother love occasionally led courts to lyrical extremes. A 1921 opinion reads,

> For a boy of such tender years nothing can be an adequate substitute for mother love—for that constant ministration required during the period of nurture that only a mother can give because in her alone is duty swallowed up in desire; in her alone is service expressed in terms of love. She alone has the patience and sympathy required to mold and soothe the infant mind in its adjustment to its environment. The difference between fatherhood and motherhood in this respect is fundamental. (41, p. 827)

In a similar vein the following was written in 1938:

> There is but a twilight zone between a mother's love and the atmosphere of heaven, and all things being equal, no child should be deprived of that maternal influence unless it be shown there are special or extraordinary reasons for so doing. (42, p. 205)

As late as the 1960s a judge wrote the following regarding the presumption that young children should be placed in the custody of their mothers:

> It is something more than sentimentalism that has led the courts to come to this conclusion. That there is no substitute for the love, companionship, and guidance of a good mother hardly needs any argument. She has the time and opportunity of providing care and comfort to children at times when normally the father is away from home. In many other ways she is the one to whom the children normally look for guidance. (43, p. 784)

Although the decisions have of late lost some of their more colorful rhetoric, the advantage of the mother over the father in custody disputes has continued to be vastly superior in spite of the legislated equality between the sexes (44). Although never legislatively stated, there has been a very strong presumption in favor of the mother (45). In the 1960s it was estimated that the mother was given custody in 90% of contested cases (46). Several years ago writers noted that "instead of equality as between parents the mother's claim to the child is paramount" (47, p. 512). In 1965 a legal observer noted that "regardless of the statutory language as to the equality of parental rights in a custody proceeding, the mother, due to the mystique of motherhood, has an advantage which will be decisive unless she is clearly shown to be unfit" (40, p. 29). This great imbalance regarding the right to custody appears to be changing, however. This will be discussed below.

Parental Culpability

Parental culpability has long been a major determinant in custody decisions. In the nineteenth century the child's best interests were generally thought to be best served by awarding custody to the parent not at fault for the divorce.

An 1857 court wrote,

> The paramount legal right of the father to the custody and education of his child can be interfered with . . . only where he has been at fault in bringing about the separation. It has never been dreamed that, when the mother has been at fault in the occurrences preceding the separation, she should be rewarded for her faults by the interposition of the court. If she breaks up the household and departs from her husband's house, wrongfully, whether it be done of her own purpose, or from weakly yielding to the evil influences of others, she is not to be allowed to take with her the children of the union. (48, p. 31)

The rationale for awarding custody to the innocent party in divorce was provided in an 1873 text:

> One who has conducted either well or ill in a particular domestic relation, will conduct the same in another; and so, as a general practice, the courts give the custody to the innocent party; because, with such party, the children will be more likely to be cared for properly. (49, p. 446)

Using this reasoning, a 1909 opinion explained that the awarding of custody to the innocent party is based "on the theory that better treatment may be anticipated from a person who has observed the marriage vows than from him who has violated them" (50, p. 601).

The emphasis on culpability was particularly marked in the case of adultery. The custody of a 3-year-old girl was awarded to the father in an 1858 case in which the mother's adultery was an issue. The opinion read; "A woman who has been guilty of adultery is unfit to have the care and education of children, and more especially of female children, nor is she entitled to the support out of the husband's estate" (51, p. 263).

Legal texts spanning the 128 years between 1852 and 1968 have reported the inclination of courts to award custody to the innocent party in a divorce, particularly when adultery is involved (20, 31, 38, 44, 52, 53). There are indications that the importance of parental culpability as a guide for awarding custody might have slightly diminished recently.

RECENT DEVELOPMENTS

A variety of important changes have been taking place in the last several years. The mother's superior right to custody appears to be diminishing. There have been changes in the courts and increasing pressures from outside the legal system that are likely to lead to an increasing orientation of the court to the needs of children.

Tender Years Presumption

The tender years presumption has long been the mainstay of the mother's superior right to custody. Change in reliance on the tender years presumption signals perhaps the greatest of the recent developments in the area of interparental child custody disputes. A 1971 Missouri court stated that "the rule giving the mother preferential right to custody . . . is predicated upon the acts of motherhood—not the fact of motherhood" (54, p. 742). A case awarding custody to the father in the absence of unfitness of the mother stated, "The 'tender years presumption' is actually a blanket judicial finding of fact, a statement by a court that, until proven otherwise . . . mothers are always better suited to care for young children than fathers" (55, p. 287). The court went on to say that "the 'tender years presumption' should be discarded because it is based on outdated social stereotypes rather than on rational and up-to-date consideration of the welfare of the children involved" (55, p. 288). Students of this problem concluded,

> The assumption that the mother is a better custodial parent was and is wrong from a historical, economic, sociological, and philosophical point of view. The notion is unfounded because it fails to project the family unit into the post-divorce reality where the mother must assume both a mother's and a father's role (56, p. 53)

The improved economic potential of women has also been recognized in that the mother is increasingly being obliged to contribute to support. In 1975 cases, the sharing of a child's expenses for summer camp was ordered (57), and a father's child support payments were set in relation to the mother's earning capacity in contrast to what her actual earnings were (58). In spite of these indications of change, however, the tender years presumption continues to be a determinant in cases (59), and it remains in the statutes (60).

Sex Discrimination Between Parents

The issue of sex discrimination per se in custody awards is a subject of new concern. The tender years presumption, which holds the young child uniquely in need of maternal care, constitutes differential treatment of the parents on the basis of their sex and is therefore a suspect classification (61, 62) under the Fourteenth Amendment's equal protection under the law clause. This issue was addressed in a 1974 Illinois opinion that stated, "Equality of the sexes has entered this field. The fact that a mother is fit is only one facet of the situation, and standing by itself, it does not authorize a denial of custody to the father" (63, p. 585). Similarly, recent cases have expanded the father's right to his illegitimate child (64–67).

The father is now more often being awarded custody even when the mother is not demonstrably unfit. In 1969 two cases awarded custody to the father, the mother in each case simply being judged less able to meet the demands of childrearing (68, 69). A decade earlier these mothers would likely have been awarded custody because they were not unfit. Even in the absence of flagrant maternal misbehavior or disability courts are more free to award the child to the father when they decide that the child's welfare requires it (70–73).

Parental Culpability

In the past, culpability of one parent with regard to fault for the divorce was almost certain to influence the court to award the child to the innocent spouse. Adultery of one parent usually assured loss of custody of the child.

As the courts have become somewhat more cognizant of the complexities of human relationships, there has been some movement in the area of family law toward relying less on culpability as a means of resolving disputes. There are growing trends toward no-fault divorce and toward the court's making more of an effort to determine whether parental disabilities or misbehavior are likely to interfere with parenting ability. For example, maternal adultery does not of itself deprive the mother of custody to the degree that it once did (74). In recent cases a mother living with a man extramaritally was awarded custody (75), and a father living in similar circumstances was allowed visitation (76).

It must be remembered that this discussion regards a nascent trend. The emphasis on parental culpability appears to have suffered only a slight decline. A focus on culpability provides a convenient formula for deciding very difficult issues; such conveniences are not easily given up. In addition, the emphasis on culpability has other derivatives; e.g., the awarding or the deprivation of custody of a child has some connotations of rewarding or punishing parents (77). The human penchant for obscuring difficult decisions with a moralistic overlay of right and wrong or reward and punishment can be relied on to maintain culpability as an eternally important issue. Nebraska law still does not allow an adulterous mother to have the custody of her child (78), and Maryland's no-fault divorce law creates a presumption against custody by an adulterous mother (79). California's no-fault divorce law excludes fault as an issue in divorce proceedings but not in custody disputes, in which fault remains a major issue (80).

Consideration of the Child's Needs

The fourth important area of change is the only one that is primarily child oriented. The appointment of a

guardian ad litem in custody disputes has become more common in recent years (81, 82). However, when agreements concerning custody have been made by the parents before the hearing the guardian ad litem has not generally been appointed (83), and the court has tended to accept whatever disposition of the children has been agreed on by the parents. However, a 1975 Wisconsin decision was nullified and the matter returned to the lower court because that court had failed to appoint a guardian ad litem to consider the custodial issue (84).

In 1974 the American Bar Association approved the Uniform Marriage and Divorce Act, model legislation that will influence new state laws (85, 86). It contains three proposals that would improve somewhat on current practices (87). First, access to litigation to modify custody is prohibited for 2 years after the issuance of a custody decree in the absence of evidence of serious harm to the child. Second, the court may appoint for the child an attorney who has more prerogatives than the guardian ad litem. Third, the court may order a custody investigation, which may include professional consultation. As is the case with the appointment of the guardian ad litem in current practice, the Uniform Marriage and Divorce Act proposals would limit the appointment of counsel and the ordering of a custody investigation to contested cases (88). However, a decision of a lower court in Pennsylvania that honored a parental custody agreement was recently nullified, and the lower court was ordered to make an investigation of the possible custody situations so that it could decide what was best for the children (89).

Child Custody in the 1970s

An 1850 treatise contains a passage that still applies:

> The state of the law relating to the custody of the persons of infants is not very satisfactory. Not only are there defects which can, perhaps, be remedied only by the authority of the Legislature; but there prevails an uncertainty in the application of the law, as it exists, to the difficult cases which frequently arise in connection with the disposal of minor children. (90, p. 7)

In 1850, divorce-related custody problems were uncommon in comparison with today. When the federal Constitution reserved the regulation of marriage to the states, there was no established mechanism for states to deal with divorce because there were no ecclesiastical courts in the new nation. Because of social and religious emphasis on the indissoluble nature of marriage, this lack did not at first present much of a problem. Initially, divorces were granted by special legislative acts, but general divorce laws began to be enacted in the middle of the nineteenth century (91). There were an estimated 10,000 divorces in 1867 (.3 per 1,000 population) (92). In 1973 there were 913,000 divorces (4 per 1,000 population) (93). Divorce, with its attendant developmental liabilities (94), is affecting vast numbers of children and poses a problem of much more than just academic interest.

The major recent changes relating to the custody of children revolve about alterations in the relative advantages of parents with respect to custody. The weakening of the tender years presumption, the increasing concern about discrimination by sex, and the moderate decrease in emphasis on parental fault in awarding custody all herald a trend toward equalization of the struggle for custody between former spouses. An important effect of this equalization is that it requires judges to exercise ever-increasing freedom or discretion in each interparental custody decision.

The child's interests may have more importance in the courts at present because of the trend toward equalization of the rights of parents. With fewer parent-oriented formulas available as guidelines, courts appear to be inclined to try to learn more about the needs of the child. As mentioned above, there has been a moderate increase in the court's considering children's needs with regard to appointment of a guardian ad litem and making custody investigations.

Psychiatric interest in this area has been a factor of growing importance. Anna Freud's seminars at Yale Law School led to publication of an influential law review article in 1963 (95). In a 1969 article Watson developed a technique for determining the psychological best interest of the child involved in a custody dispute (96). In 1973 Goldstein and associates published *Beyond the Best Interests of the Child* (97), which is being widely read within both the legal and the mental health professions. These publications are serving to make lawyers and judges much more aware of the problematic situations facing children in custody contests as well as the importance of making the decisions conform to the developmental needs of the children involved.

CONCLUSIONS

The current situation regarding custody contests in the courts has some analogies to the period at the end of the nineteenth century, when the primary right of custody began to shift from father to mother. The major recent changes revolve about alterations in the relative advantages of parents with respect to custody. The trend toward equalization of parental rights has decreased judicial reliance on parent-oriented formulas for decision making in interparental custody disputes. I have elaborated elsewhere (83) the function of these presumptions in providing a structure that relieves judges of some of the extremely broad discretion they possess (and often dread). In addition, there is a growing awareness of the importance of determining the child's emotional and developmental needs and relating them to the people and environments being contested in court.

As a result of these recent influences it is likely that courts will increasingly call on psychiatrists and other mental health professionals to aid in these difficult decisions. It is also to be expected that the psychiatrist's

role as "child development consultant" (83, p. 797) will be subject to further development and definition. At the present time, some rigid assumptions of long standing are gradually being eroded. The opportunity may now exist to enhance appreciably the rights of children in custody disputes. With the active participation of the psychiatric profession, the child and his or her needs can become and remain the focal issue in custody contests.

A New Section in the *Journal*

The *Journal* is pleased to announce the inauguration of a new section, "Clinical and Research Reports," which will appear monthly beginning with the January 1977 issue. This section will include reports on new clinical or laboratory observations, single cases of unusual interest or importance, descriptions of preliminary studies, and well-developed suggestions for future research. Reports should not exceed 1,000 words and may contain at most 1 table and 8 pertinent references (figures will not be used). Submissions will be reviewed by at least one referee and the Editor. It is anticipated that the publication lag will be considerably less for Reports than for other articles in the *Journal*. Submissions are welcome immediately; authors will be informed by postcard of the disposition of their papers.

Reports should be submitted in duplicate, double-spaced, with tables and references typed on separate sheets. The designation "Clinical and Research Reports" should appear in the upper right corner of the title page, and complete addresses and affiliations, as well as a telephone number of the author designated to handle correspondence, are required.

Generic and Trade-Name Antipsychotic Drugs: Clinical Equivalence

BY CHING-PIAO CHIEN, M.D., RICHARD LABRIE, PH.D., CHOONG-GUEN PARK, M.D., JONATHAN O. COLE, M.D., AND WILLIAM M. WERNER, M.D.

The clinical inequivalence of generic versus trade-name drugs has been reported for nonpsychiatric drugs but rarely for psychotropic drugs. Recent expiration of patents on some psychotropic drugs has made the evaluation of the clinical equivalence of generic versus trade-name drugs a matter of interest from methodological, sociopolitical, and economic aspects. The authors discuss these points, with emphasis on methodology, in their report of a double-blind study of the efficacy of chlorpromazine and Thorazine in the treatment of 54 acute schizophrenic patients. An analysis designed to infer the maximum possible advantage of Thorazine over generic chlorpromazine indicated that differences between the two were clinically insignificant.

FOR AT LEAST the past 10 years there has been a heated professional and political debate over the virtues and weaknesses of generic drugs. Some of the concern has grown from the vast expansion of third-party payment systems providing coverage for the treatment of illness and the rapidly rising costs of such coverage. Even though expenditures for drugs constitute only a minuscule proportion (1%) of hospital costs (1), the apparent affluence of the pharmaceutical industry has made the attacking of drug costs, the deification of generic (i.e., inexpensive) drugs, and the vilification of brand-name (i.e., expensive) drugs a favorite indoor sport for both politicians and health administrators. On the other hand, representatives of organized medicine and pharmacy (2, 3) have attacked the use of generic drugs because of their alleged inferiority to brand-name products. Sadove (4) cited 31 factors that could significantly differentiate a generic drug from a brand-name product. They include size of crystal or particle, its forms, and isomers; coatings, number, and types; diluent; pH; solubility; ionization of ingredients; surface tension-surface active agents; and dissolution and disintegration rate.

There is reasonable evidence that the generic form of some drugs (principally antibiotics but also tolbutamide and diphenylhydantoin) provides significantly inferior blood levels of the active agents (2–8). An anesthesiologist has documented some practical problems that he has encountered using generic drugs, often in the form of injectable preparations (9).

Until recently, the issue of generic equivalence in psychopharmacology has been moot simply because all of the new and more effective drugs—antipsychotic, antidepressant, and antianxiety agents—were made under patents that are only now beginning to expire. The exceptions to the rule have not provided the incentive to develop the needed comparative methodology. Reserpine, a common drug in the treatment of hypertension, has not been used recently in the treatment of schizophrenia. *d*-Amphetamine has not been widely used in psychiatry. The generic form of meprobamate became available 10 years ago due to a complicated legal situation. However, because the usefulness of meprobamate is restricted almost exclusively to mild and often transitory emotional or musculoskeletal conditions where it is only slightly better than placebo (10), one might never be able to determine whether or not the generic form is equal to Equanil or Miltown. Lithium carbonate, the only other generically marketed medication among the newer drugs, is not metabolized by the body, and monitoring of blood levels has replaced clinical tests of equivalence.

The recent expiration of the patent on chlorpromazine presents the first opportunity and incentive to establish a methodology for testing clinical equivalence of the effectiveness of generic chlorpromazine and the trade-name drug, Thorazine. Current trends noted in the Food and Drug Administration's acceptance of lithium carbonate (where 3 companies were required to perform efficacy trials of their products despite overwhelming evidence from abroad that lithium carbonate was effective in the treatment of mania [11]) suggest that generic equivalence is not likely to be determined solely by chemical identity but will also entail testing equivalence in clinical therapeutic effect.

In a study of generic chlorpromazine (12), chronic hospitalized patients were treated in a crossover design. Not only is such a design a time-consuming procedure but, given the increasingly large number of treatment-

Dr. Chien is Professor of Psychiatry, Albany Medical College, Albany, N.Y. 12208. Dr. LaBrie is President, LaBrie Associates, Cambridge, Mass. Dr. Park is Chief, Department of Evaluation and Research, and Dr. Werner is Director, Creedmoor Psychiatric Center, Queens Village, Queens, N.Y. Dr. Cole is Lecturer in Psychiatry, Harvard Medical School, Boston, Mass., and Chief, Psychopharmacology Program, McLean Hospital, Belmont, Mass.

Drugs were provided by Mr. William Mounce of Franklin Laboratories, Philadelphia, Pa.

resistant chronic patients available for study, it also seems quite possible that neither form of chlorpromazine might have any major effect on psychopathology. Proving equivalent ineffectiveness could be a very unsatisfying pursuit. A direct comparison of generic chlorpromazine with Thorazine in newly hospitalized patients is a more critical test of the similarity of therapeutic efficacy. In our opinion, the ability of an antipsychotic drug to markedly reduce psychopathology in acute patients is more crucial than the drug's ability to modulate psychotic symptoms in chronically institutionalized patients.

The opportunity presented by this comparison of a generic with a standard brand-name phenothiazine led us to also reevaluate available statistical approaches to this problem. The approach we used does not simply say that the two drugs were not statistically significantly different from each other. Instead, it provides a reasonable outer limit, in terms of the measures used in the study, for the greatest probable difference between the drug forms studied, on the conservative assumption that the real difference found in the study might, by chance, have unduly favored the generic drug.

METHOD

Fifty-four patients newly admitted to one unit of Creedmoor State Hospital who, in the judgment of the treating physician, required antipsychotic medication were randomly assigned to Thorazine (N=23) or generic chlorpromazine (N=31).[1] Patients with physical illnesses contraindicating antipsychotic drug therapy were excluded from the study. Those who had been medicated continuously for more than 2 days immediately before admission were not recruited for the study. The patients were assigned to the same treating physician throughout the study period in order to ensure the consistency of the prescribing pattern. Patients were given a routine clinical diagnosis as well as a computer diagnosis using Overall's procedure (13) with the Brief Psychiatric Rating Scale (BPRS) (14).

The procedure developed by Overall combines the BPRS ratings to obtain composite scores characteristic of 13 psychiatric stereotypes. These scores are further reduced to 3 scores that have been shown to discriminate among the following major conditions: high depression versus low paranoia, schizoid versus others, and manic versus others. The mean discriminant scores for the 2 drug groups were compared using a procedure for testing the differences of several means (Hotelling's t^2). The 2 groups did not differ in their major psychiatric symptoms as measured by the BPRS. As indicated in table 1, there were no significant differences between the groups in other pretreatment measures and demographic data, such as age, age at onset of illness, number of previous hospitalizations, and total scores on the BPRS and the Nurses' Observation Scale for Inpatient Evaluation (NOSIE). Men comprised 48% of the Thorazine group and 32% of the generic chlorpromazine group. Physicians' ratings of severity of illness were as follows: mild, 9% for the Thorazine group and 7% for the chlorpromazine group; moderate, 65% versus 58%; marked, 13% versus 32%; and severe, 13% versus 3%.

TABLE 1
Pretreatment Characteristics of the Two Study Groups

Item	Thorazine (N=23) Mean	Thorazine (N=23) SD	Chlorpromazine (N=31) Mean	Chlorpromazine (N=31) SD
Number of previous hospitalizations	2.65	1.70	2.63	1.60
Age at onset of illness (years)	21.60	12.30	25.50	9.80
Present age (years)	40.20	13.30	43.70	14.40
BPRS total score	51.00	11.50	52.10	10.60
NOSIE total asset score	69.80	11.30	64.60	15.50

During the 4-week study period that began immediately after the baseline ratings were obtained (usually on the first day of hospitalization), only oral antipsychotic medication was given. In this double-blind study, tablets containing 50, 100, and 200 mg of chlorpromazine were available for each patient in individually numbered containers. Dosage was determined by the treating physician, with no upper limit specified. If the patient's psychiatric state necessitated parenteral medication, intramuscularly administered sodium amytal was used. Antiparkinsonian medication was not routinely given but was available as needed to treat emerging neurological side effects.

RESULTS

Therapeutic Effect of Chlorpromazine Treatment

All patients showed marked improvement during the 4-week study period regardless of drug received. Table 2 shows the groups' total mean scores on the BPRS and NOSIE before treatment, at 2 weeks, and at 4 weeks. The BPRS has a total minimum score of 18 when all characteristics of symptoms are rated as absent (1 point each) and a theoretical maximum of 126 when all symptoms are rated as extremely severe (7 points each). The week 4 ratings for each drug group showed an approximately 73% reduction in symptoms. It is clear that both drugs produced significant therapeutic improvement in most of the patients. The Thorazine group showed significant improvement on 16 of the 18 BPRS items and the generic chlorpromazine group, on all 18 items.

Nurses' ratings of the patients' ward behavior using the NOSIE schedule also showed major improvement, with a total improvement of 19% for the Thorazine

[1]Informed consent was obtained from all the patients after the nature of the procedure had been fully explained.

TABLE 2
Changes in Total Mean Scores for the Two Study Groups

Measure	BPRS		NOSIE	
	Thorazine (N=23)	Chlorpromazine (N=31)	Thorazine (N=23)	Chlorpromazine (N=31)
Pretreatment	51.00	52.10	69.80	64.60
Week 2	35.91	37.39	79.00	71.93
Week 4	26.35	27.42	81.17	79.19
Change to week 2	−15.09*	−14.71*	9.22**	7.36***
Change to week 4	−24.65*	−24.68*	11.39**	14.61***

*p=.001, paired t test.
**p=.01, paired t test.
***p=.05, paired t test.

patients and 28% for the generic chlorpromazine sample. By the end of the study period the Thorazine group showed significant mean changes on 5 of the 7 NOSIE scales, and the generic chlorpromazine group on 6 scales.

Physicians' and nurses' clinical global ratings of improvement at 4 weeks indicated that only 3 of the 54 patients (5.6%) showed no change; all the others were rated as improved, with 16 patients (30%) rated as much improved. A total of 50 patients (93%) were rated by physicians as at least moderately ill at the beginning of the study, compared with only 9 (16%) at the end of the study.

Manifest side effects (e.g., drowsiness, rigidity, tremor) were slightly, but not significantly, more common among Thorazine patients (53% versus 41%).

Differences in Treatment Schedules

The study was designed to allow the treating physician, who was blind to the type of actual preparation, to determine the effective dosage for each patient. Under these conditions the generic chlorpromazine patients received, on the average, 21% more drug than did the Thorazine patients. The mean dose of Thorazine was 384 mg every day, and the mean dose of generic chlorpromazine was 463.8 mg every day. The wide range of doses employed in this and generally all clinical settings produced large and nearly identical standard deviations of 298.2 for the Thorazine group and 298.1 for the generic chlorpromazine group. The difference between means was not statistically significant (t=0.955, p=.35). Dosage was significantly related to improvement as measured by the BPRS total score at weeks 2 and 4, NOSIE total assets at weeks 2 and 4, nurses' ratings of severity of illness at weeks 2 and 4, and physicians' ratings of severity at week 2.[2] Because of the positive correlation between amount of drug and amount of improvement and the larger average doses for the subjects receiving generic chlorpromazine, the analyses of outcome were adjusted for the amount of drug received.

Comparative Therapeutic Effect of Two Preparations

The analyses of covariance, adjusted for amount of drug received, failed to reject the null hypothesis of no difference between drug treatments for all the major outcome measures.[3] The analyses of the individual scale items showed that subjects receiving Thorazine had made greater improvement at week 2 on the NOSIE ratings of social competence and retardation and the BPRS rating of disorientation.[4] These differences disappeared by week 4, when no individual scores were significantly different between the 2 drug groups.

After adjustment for the larger average dosage of generic chlorpromazine, the outcome measures did not show any instance where the 2 drug treatments were significantly different at the end of the study period. The 2 drug formulations were equally effective in producing major improvements in the mental status of the patients.

Test of the Similarity of the Two Preparations

Unfortunately, classical tests of the difference between 2 groups, as those reported, emphasize the reduction of type I error (the probability of finding a difference when no difference exists). In a direct comparison where the tests fail to reject the null hypothesis, one is left to consider type II error (the probability of finding no difference when a true difference does exist). Establishing the amount of type II error in a statistical comparison is not possible without knowing the "true" difference. LaBrie and associates (15) have reported on the procedure for inferring the limits of the true difference when type II error is at a minimum. Briefly, the procedure is to establish the maximum relative superiority for the standard that may be inferred from the observed differences and the standard error of those differences.

Classical procedures reduce error with an increase in the number of observations and thus increase the significance of observed differences. Under such conditions, small and perhaps not clinically useful differences might reach the level required to reject the null hypothesis of no difference. LaBrie and associates' procedure does not penalize researchers for attempting to gain precision with larger samples of patients, but rather uses the decreased error from such experi-

[2]There was no indication of significant curvilinearity in these relations as determined by fitting a quadratic equation to the data.

[3]Analysis of covariance may not provide a perfect adjustment for dose differences, but given the absence of significant curvilinearity and dose differences, any remaining treatment differences not completely adjusted for by the covariance analysis must be considered slight.

[4]A total of 50 tests of group differences were performed. At the chosen level of significance (p=.05), 2.5 of these 50 tests could be expected to be significant by chance when no difference existed between the groups. The three differences noted are nearly the expected number of significant differences that would result from chance.

TABLE 3
Inferred Maximum True Differences Between the Two Groups

Measure	Adjusted Means		Standard Error of Difference	Observed Mean Difference	Maximum Probable Thorazine Mean	Maximum Probable Mean Difference
	Thorazine	Chlorpromazine				
BPRS total score	26.76	27.01	2.24	0.25	23.10	3.91
Change to week 4	24.60	24.73	3.37	0.13	30.10	−5.37
NOSIE total asset score	80.53	79.83	4.24	−0.70	87.50	−7.67
Change to week 4	10.73	15.28	4.08	4.55	17.50	−2.22
Physicians' rating of severity, week 4	2.25	2.39	0.30	0.14	1.76	0.63
Nurses' rating of severity, week 4	2.99	2.93	0.30	−0.06	2.50	0.43

ments to more accurately and narrowly define the limit of possible true difference.

To attempt to clarify this issue, the concept of the critical ratio must be introduced. For most tests of significance used in clinical studies the means of the observations and the standard deviations of these observations are presented. The critical ratio is the ratio of the difference between the means to the standard error of the differences; this allows treatment contrasts to be expressed in standardized units independent of the actual measurements employed in the study.

Given the critical ratio of the differences between 2 drug treatment groups in a clinical study, one can calculate the probability that the difference would be observed if the groups were the same. This is the usual test for differences between types of treatment. One can also use this statistic to determine what the biggest difference between the 2 treatments could be, given that the observed actual study differences might occur with a probability of no less than 1 in 20 ($p=.05$). One can therefore state with some assurance that the biggest probable difference between 2 similar treatments is of a specific size. The method used in this study gives such an answer. This difference can then be interpreted clinically as to its meaningfulness.

The results of applying this procedure to the global outcome measures in this analysis are reported in table 3. The table should be read in the following way. The observed mean difference on the BPRS total score was 0.25, while the maximum probable mean difference was calculated to be 3.91 at the 5% level. BPRS change from baseline to week 4 showed an observed difference in favor of generic chlorpromazine of 0.13 scale points; the maximum probable mean difference in favor of Thorazine was − 5.37 scale points.

Differences in Dosage Schedules

Because the treating physician was responsible for determining the dosage schedule of each patient, we can analyze the relative amounts of drug given each group and the number of changes in dosage. As reported earlier, the group receiving generic chlorpromazine was given 21% more drug than the Thorazine group. This difference was not statistically significant. The Thorazine group required an average of less than 1 change in dosage during the trial period (mean=0.609), while the generic chlorpromazine group required significantly more (mean=1.194, $p=.05$). Since most of the study patients had been admitted to the same hospital before, the treating physician was able to consult their records and start from the dosage that had previously been considered optimal. This may account for the relatively infrequent change in dosage. Furthermore, the random assignment of patients to 2 drug groups equates the distribution of the 2 groups among each of 3 treating physicians so that the differences in the physicians' prescribing patterns are also equally distributed between the groups.

In summary, the experience provided by this study indicates that the treating physicians made significantly more dosage adjustments in the generic drug and eventually prescribed larger doses of it. Thus the generic formulation used in this study is a little less potent on a milligram/kilogram basis, and treatment with the generic formulation may require more adjustments to achieve the most effective dosage. However, treatment response in our study was not affected by the difference in frequency of dosage change.

CONCLUSIONS

Other investigators have reported the inequivalence of generic and trade-name nonpsychiatric drugs. However, the issue of generic equivalence in psychopharmacology has just recently begun to receive attention. The impetus behind this concern was primarily triggered by the expiration of patents on some popular psychotropic drugs and the proposed legislation for using inexpensive generic drugs for recipients of public assistance. In this study we attempted to explore a method of data analysis for evaluating the similarities and differences between a generic and a trade-name psychotropic drug.

Fifty-four newly admitted patients who required antipsychotic medication were randomly assigned to Thorazine or generic chlorpromazine. Dosage was determined by the treating physician. At the end of the 4-week study most of the patients showed significant improvement; there was no significant difference between the 2 groups as measured by the BPRS, NOSIE, and physicians' and nurses' ratings of severity of illness. Analysis designed to infer the maximum possible advantage of Thorazine over generic chlorpromazine indicated that differences between the 2 drugs were clinically insignificant.

We found that due to the relatively wide range of therapeutic dosage in a given neuroleptic, the differential therapeutic efficacy between generic and tradename neuroleptics may not be a serious problem in clinical practice if the inferred maximum true difference between the two drugs is not remarkable.

Self-Reports Versus Sleep Laboratory Findings in 122 Drug-Free Subjects with Complaints of Chronic Insomnia

BY MARY A. CARSKADON, WILLIAM C. DEMENT, M.D., PH.D., MERRILL M. MITLER, PH.D., CHRISTIAN GUILLEMINAULT, M.D., VINCENT P. ZARCONE, M.D., AND RENE SPIEGEL, PH.D.

The authors compared the sleep laboratory recordings of 122 drug-free subjects who complained of chronic insomnia with the subjects' estimates of their habitual sleep characteristics and their estimated sleep time on the morning after sleeping in the laboratory. Most subjects consistently underestimated the amount of time they slept and overestimated the amount of time it took them to get to sleep in comparison with laboratory data. All subjects consistently underestimated the number of arousals they experienced. The authors discuss the implications of these findings for the treatment and definition of insomnia and for further research.

SEVERAL SURVEYS (1–6) have suggested that the number of people in the United States who complain of insomnia may well be in the millions. One of the most provocative of these surveys, because insomnia was not its specific focus, was Hammond's prospective study of risk factors in coronary heart disease, stroke, and cancer, in which 1,064,004 men and women were surveyed (2). Hammond and Garfinkel (2, 7) found that 13% of men and 26% of women over the age of 30 surveyed complained of insomnia. The incidence of the complaint increased with age, reaching a plateau in the fifth decade. In addition to these prevalence data, Hammond and Garfinkel also presented evidence that the complaint of insomnia is an important mortality risk factor.[1]

Another indication of the magnitude of the insomnia problem is the size of the industry involved in treating the complaint. For example, Balter and Levine (8) estimated that the cost for retail prescriptions of hypnotics in 1970 was $170,000,000. This widespread use of hypnotic medications has also made accidental overdosage in people using or abusing these compounds a substantial health hazard (9).

In contrast to the scope of the problem, the current data describing objective sleep characteristics of people who complain of insomnia are relatively sparse. At the time of writing, we were able to locate 20 reports of polygraphic sleep studies in clinically defined insomniac patients (10–29). The number of patients in these reports ranged from 1 to 20 (mean=8), and the number of drug-free or placebo nights recorded for each patient ranged from 1 to 10 (mean=3). Most of the samples were small and from many different laboratories, with whatever variability the local technology and procedures may have introduced; there was also tremendous variation in the sample characteristics, duration of the complaint, and recent use of hypnotics. In the cases of multiple papers from a single laboratory, it was often very difficult to know whether the same patients were reported in 2 or more publications. Another serious problem was the failure to specify whether the patients were taking sleeping pills at the time of the study or the duration of drug withdrawal if they were said to be drug free. Data from patients who had abruptly withdrawn from sleeping pills shortly before the recordings might have been artifactual (30). Well over half of any large population of individuals who complain of insomnia are likely to be using one or more sedative drugs on a daily basis (31). We may conclude that these studies do not provide a reliable description of insomnia; their extreme variability defies a coherent summary.

Somewhat more systematic studies have been carried out on nonclinical populations of self-defined "poor sleepers," restless sleepers, and the like, e.g., Monroe's classic investigation (32). However, these nonclinical groups may represent a different population from patient groups.

A large, standardized, "definitive" laboratory study of thousands of patients complaining of insomnia is certainly not feasible at the present time. Nonetheless, it is hoped that satisfactory progress can be made

[1]Everyone interested in sleep disorders is indebted to Dr. Daniel Kripke for calling attention to these data. Dr. Kripke is now in possession of Hammond's raw data and is attempting to show relationships with other risk factors that might help interpret the effect of this sleep complaint on life span.

through systematic accumulation of data on larger samples of patients by various laboratories involved in clinical sleep studies. Our own case series of individuals who complained of chronic insomnia and who have been studied polygraphically in a drug-free condition now numbers 122. This paper will describe the relationship of their self-reports on their sleep characteristics to objective sleep laboratory recording values. Subsamples of the same group of 122 subjects have been reported on elsewhere (33–35).

SUBJECTS

The 122 subjects reported on in this study were drawn from two general groups whose sleep was recorded between 1970 and 1975. All of the subjects gave informed consent for sleep recordings. Patients referred by physicians to the Stanford University Sleep Disorders Clinic for evaluation of a complaint of chronic insomnia accounted for 59 of the subjects. The remaining 63 were recorded while they were participating in specific research protocols, usually involving the evaluation of hypnotic compounds. Of the 63 volunteers who were accepted for study, 48 had consulted physicians for their sleep problems.

In order to determine whether the two sources of subjects resulted in substantial differences in sleep, the subjects referred from each source were compared on the basis of 13 variables used to characterize sleep. These 13 variables included total sleep time; sleep latency; percentage of sleep time; wake time after sleep onset; number of arousals lasting 15 seconds or longer; minutes of stages 1, 2, 3, 4, and REM sleep; estimated total sleep time; estimated sleep latency; and estimated number of arousals. Only 1 variable showed a significant difference between the two subject sources: the number of arousals was higher ($p<.01$, Student's t test) in the clinic patients (mean=20.9 arousals) than in the subjects who volunteered for research studies (mean=15.0 arousals). Because this was the only difference, we felt that the 122 subjects were representative of people with chronic complaints of insomnia severe enough for them to consult a physician and therefore should be considered as a single group.

Patients who were found to have sleep apnea (36) were not included in this summary, nor were a small group of patients found to have nocturnal myoclonus (37) whose sleep measurements have been reported elsewhere (38). Although we are quite certain that none of the 122 individuals reported on in this article had sleep apnea, we are not sure that the same applies to nocturnal myoclonus because many of the patients were studied before the condition was specifically ruled out.

All subjects were drug free at the time of the sleep recordings. Drug-free status was generally verified only by subject report; however, many patients followed in the Stanford Sleep Disorders Clinic had completed a specific drug withdrawal program before the recording sessions. If a patient's report was clearly doubtful, blood and urine samples were tested. The sleep recording itself was also helpful in verifying drug-free status because most hypnotics produce characteristic effects on overall EEG patterns. Two volunteers were dropped from consideration on this basis. The length of the drug-free period preceding the laboratory sleep recordings varied from subject to subject. However, with very rare exceptions, it was not less than 1 week and was typically (in over 80% of the group) more than 2 weeks.

The subjects in this study included 59 women aged 18 to 65 years (mean=47.9; SD=10.8) and 63 men aged 19 to 68 years (mean=45.7; SD=12.4).

METHOD

The subjects were studied over a 5-year period under several clinical protocols. Typically, they either had several consecutive nights of recording as part of a routine clinical diagnostic evaluation, or they participated in a study involving evaluation of efficacy of hypnotic medication, which always included a series of nondrug (placebo) nights before the active compound was administered.

Regardless of the protocol, certain standard sleep recording procedures were observed in every case. All subjects were recorded in individual darkened sound-attenuated bedrooms at times that approximated their habitual sleeping hours. The recordings always included monopolar EEG (recorded from a standard central placement), eye movements (electro-oculogram), and chin electromyogram. Thus, although certain subjective and preliminary questionnaire data are missing for several subjects, comparable sleep recording data were obtained in every case. Each subject had at least 2 consecutive all-night sleep recordings, the first of which was considered adaptation and excluded from the analyses. (In 25 cases, the first 2 nights were considered adaptation and were not analyzed.) For the most part, subjects were permitted to sleep until they awakened spontaneously, although on approximately 20% of the nights the recording was terminated before spontaneous arousal so that subjects could get to work on time.

A total of 368 all-night sleep recordings were analyzed for this study. The number of consecutive post-adaptation all-night recordings ranged from 1 (in 49 subjects) to 13 (in 2 subjects). All sleep recordings were scored in 30-second epochs according to the criteria of Rechtschaffen and Kales (39).

Subjective data were gathered in two forms. First, most subjects received a prerecording interview that detailed areas of complaint. Second, sleep questionnaires were given before access to clocks on the mornings after the all-night sleep recordings to assess the previous night's sleep. Sleep recording data and sleep questionnaire information were averaged for each subject across the postadaptation laboratory nights.

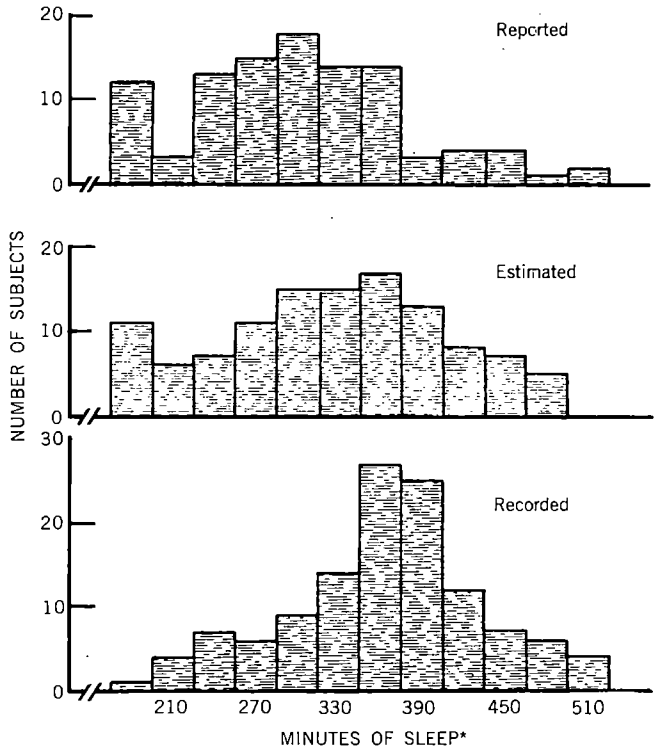
RESULTS

Complaint Background

The history of complaints of insomnia for the 40 women on whom data were available ranged from 6 months to 33 years (mean=13.1 years). The complaints of 43 men had been present from 3 to "more than 25" years (estimated mean=8.5 years). Complaints regarding nightly sleep time were similar for women and men. Mean sleep time per night for 51 women was 297.0 minutes and for 50 men was 306.1 minutes. Also similar were the habitual sleep latencies reported in the histories for women and men, with a mean sleep latency of 62.2 minutes for 51 women and 60.2 minutes for 38 men.

When 41 of the women were asked if they ever took daytime naps, 24 said they never napped, 13 said they napped less than once a week, and 4 said more than once a week. Of 32 men asked about napping, 12 reported that they never took naps, 16 said they took less than one nap a week, and 4 said they napped more often than once a week.

Sleep Data



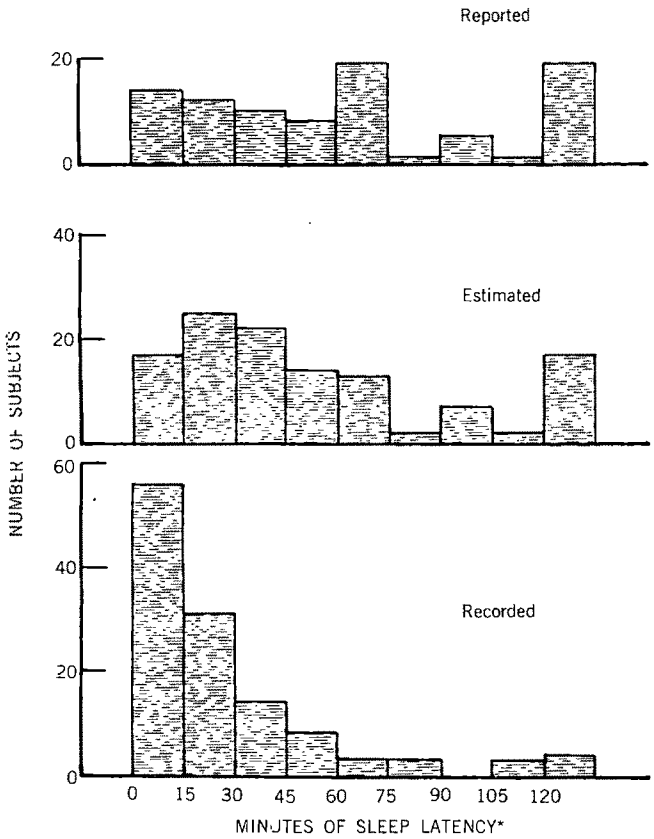
Two major complaint areas are usually assessed in patients who complain of insomnia—sleep induction and sleep maintenance. For this report these areas were evaluated using total sleep time, sleep latency, and number of arousals. These variables were chosen because they were accessible from both objective recordings and subjective reports. Two-way, age-by-sex analysis of variance was performed on each of the variables, and Spearman rank order correlation coefficients (ρ) were computed among the variables for women and for men. Significant results are reported when appropriate.

Total sleep time. Objectively recorded total sleep time showed a significant sex difference ($F=5.44$, $df=1, 112$; $p<.05$; mean for women=375.1 minutes, for men=392.2 minutes). No significant changes were seen with age. Variability among subjects was high; the range of total sleep time in the 122 subjects was 98.7 minutes to 528.6 minutes.

Subjective estimates of sleep time on the mornings after the recordings usually averaged well below the objective values. Overall, there was a significant difference ($p<.001$, t test for correlated means) between the average recorded total sleep time of 375.0 minutes and the average estimated total sleep time of 332.8 minutes. Nevertheless, there were 21 subjects whose estimates were consistently within 15 minutes of the actual total sleep time and 15 subjects who overestimated total sleep time by more than 15 minutes. Total sleep time was consistently underestimated by a margin of greater than 60 minutes a night by 42 subjects. A significant correlation between the recorded total sleep time and the estimated total sleep time was found in both women ($\rho=.40$, $p<.001$) and men ($\rho=.45$, $p<.001$).

For the subjects whose interview data were available, the correlation between the recorded total sleep time and the interview estimate of habitual sleep time was significant only in men ($\rho=37$, $p<.01$).

FIGURE 1
Comparison of Average Sleep Times of Subjects with Insomnia Complaints Reported in Prerecording Interview (N=101), Estimated After Sleeping in Laboratory (N=115), and Recorded in Laboratory (N=122)



*Each bar represents an interval of 30 minutes (minimum values for each range age given), with the exception of the first bar, which represents all values lower than 210 minutes.

Figure 1 presents a comparison of the frequency distributions of sleep time in terms of the initial self-report at the prerecording interview, the average estimated total sleep time in the laboratory, and the average sleep time on the postadaptation laboratory sleep recordings. From this figure it is apparent that the complaints about sleep time at home were distributed in a lower range than were the estimated sleep times in the laboratory. Similarly, a greater number of individuals estimated less sleep time in the laboratory than was actually recorded.

Sleep latency. For this study the objective measure of sleep latency was defined as the elapsed time from turning out the lights until the appearance in the sleep record of three consecutive 30-second epochs of NREM stage 1 sleep or the first epoch of NREM stage 2 sleep.

Sleep latency showed great variability among subjects: the shortest average sleep latency was 0.7 minutes, and the longest was 251.7 minutes. No significant age or sex differences were discernible by analysis of

FIGURE 2
Comparison of Average Sleep Latencies of Subjects with Insomnia Complaints Reported in Prerecording Interview (N=89), Estimated After Sleeping in Laboratory (N=119), and Recorded in Laboratory (N=122)

*Each bar represents an interval of 15 minutes, with the exception of the last bar, which represents all values of 120 minutes or more.

variance, and no significant correlation with age was found in either women or men.

In general, the estimated sleep latencies were higher than the recorded sleep latencies. Overall, there was a significant ($p<.01$, t test for correlated means) difference between the average recorded sleep latency of 26.2 minutes and the average estimated sleep latency of 61.7 minutes. However, 54 subjects were able to estimate sleep latency within 15 minutes of the recorded value, and 5 subjects underestimated sleep latency by a margin greater than 15 minutes. Sleep latency was consistently overestimated by more than 15 minutes in 60 subjects and by more than 1 hour in 15 of these subjects. Significant correlation was found between recorded and estimated sleep latency in women ($\rho=.64$, $p<.001$) and in men ($\rho=.60$, $p<.001$). In the 89 subjects who had reported habitual sleep latency in the prerecording interview, there was no significant correlation between the average recorded sleep latency and their reports in either women or men.

Figure 2 shows the frequency distributions of sleep latencies obtained from the subjects' initial prerecording reports and from the estimated and actual sleep latencies in the sleep laboratory. It is clear from this figure that the distribution of sleep latencies was concentrated much more in the 0–30-minute range for the recorded sleep latencies than for either of the subjective estimates. The distribution of laboratory estimates was a closer approximation of the actual sleep latency distribution than was that of the prerecording interview reports.

Nocturnal arousals. The number of arousals recorded on the laboratory nights showed a significant difference among age groups ($F=3.73$, $df=4, 112$; $p<.05$; mean values for age, 18–29 years=12.7 arousals, 30–39 years=14.3 arousals, 40–49 years=17.8 arousals, 50–59 years=18.4 arousals, and 60–68 years=25.2 arousals): the older subjects had more frequent arousals than did the younger subjects. Without exception, the subjects consistently underestimated the number of arousals. No significant correlation was found between the recorded and estimated number of arousals in either women or men. No data were available from the prerecording interviews on number of nocturnal arousals.

MMPI Data

The MMPI was administered to 65 of the subjects; 22 of these were clinic patients and 43 were from the group of research subjects. Normal MMPI profiles were found in 27 subjects (42%). (The masculinity-femininity scale was not considered.) Of the subjects who had one or more scales in the pathological range, 25 showed abnormal elevation of the depression scale, and 6 had an elevated hypochondriasis scale. Inspection of the data showed no obvious relationships between MMPI profiles and the subjective or objective sleep variables.

DISCUSSION

The relationship between subjective and objective sleep data has been examined in smaller samples by a number of investigators (11, 18, 32–34, 40–42). We are concerned in our present sample with the extent to which the prerecording complaints and the sleep logs of the morning after predicted the actual sleep.

As was noted earlier, the estimate of sleep time reported in the prerecording interview was correlated with the recorded value only in men, and the estimate of habitual sleep latency reported in the interview was uncorrelated with the recorded values in both men and women. How does this finding relate to how a physician might interpret a patient's sleep complaint? For example, an examination of the data from our 57 subjects who said they usually slept 5 hours or less each night shows that the actual recorded sleep time was under 5 hours in only 10 subjects (17.5%), between 5 and 6 hours in 10 subjects (17.5%), between 6 and 7 hours in 31 subjects (54.4%), and over 7 hours in 6 subjects (10.5%). In the 46 subjects who said they usually took 60 minutes or longer to fall asleep, we found the sleep

latency recorded in the laboratory was over 60 minutes in only 6 subjects (13.0%), between 30 and 60 minutes in 12 subjects (26.1%), between 15 and 30 minutes in 8 subjects (14.4%), and under 15 minutes in 20 subjects (43.5%). From these data it appears that fewer than 1 patient in 5 with a complaint of very short sleep or very long sleep latency will have the complaint confirmed in a laboratory sleep recording.

In terms of the estimates obtained in the questionnaires given in the morning after each recording session, the subjects were able to characterize their sleep more accurately. In both the women and men, the laboratory estimates of sleep time and sleep latency were correlated with the recorded values. Nevertheless, differences between the mean values were high—over 40 minutes for sleep time and approximately 35 minutes for sleep latency—with estimated sleep time significantly lower and estimated sleep latency significantly higher than the recorded values.

The most striking discrepancy between estimates and actual values was found for the number of arousals per night. Every subject consistently underestimated the number of arousals. The sleep processes may have interfered with memory for short arousals, subjects may have perceived numerous short arousals as one or several longer awakenings, or the short arousals may have been perceived as a continuation of unbroken wakefulness at the beginning of the night or an early interruption of sleep at the end of the night. In the men there was a trend for the number of arousals to be inversely correlated with the estimated total sleep time ($\rho=-.27$, $p<.05$), which suggests that subjective emphasis on many brief arousals may have contributed to the underestimations of sleep time.

These data relating subjective estimates to actual sleep recordings in subjects who complained of insomnia indicate that physicians should be very careful when evaluating the complaint. Because the morning-after estimates more closely paralleled the recorded values, one might conclude that people who complain of insomnia are able to describe their sleep with more accuracy on a night-to-night basis than in a more unfocused interview. This suggests that a daily sleep log would be a better way for physicians to evaluate the sleep complaints of these patients.

Comparison with noncomplaining individuals. Investigators have reported on people who complain of insomnia but who apparently obtain "enough" sleep (18, 34). In our present sample we obviously have a number of such individuals. Accordingly, we may even ask whether the sleep of this entire group can be distinguished from the sleep of normal, noncomplaining subjects. At the present time the best summary of normative sleep data is that of Williams and associates (43). In a separate analysis (35), we compared sleep time and sleep latency in 87 of Williams and associates' normal subjects with that of 109 of the subjects reported on here. Overall, the normal sleep times were approximately 30 minutes longer and the sleep latencies approximately 30 minutes shorter. Age and sex interactions were also apparent. Although there were clear differences between the groups on these variables, the values for sleep latency and sleep time overlapped the normal range in many of the subjects with sleep complaints. For example, if one were to compare the 109 subjects who complained of insomnia (35) to age- and sex-matched normal subjects (43), 42 (38.5%) were within one standard deviation of the normal mean for sleep time and 57 (52.3%) for sleep latency. In addition, 12 (11.0%) "insomniacs" were above the range for sleep time and 2 (1.8%) were below the range for sleep latency. Thus it appears that approximately half of the subjects who complained of insomnia could not be distinguished from normal subjects by total sleep time or sleep latency.

In an unpublished study we also compared our subjects with Williams and associates' normal subjects for the number of arousals per night. The number of arousals was higher in the subjects who complained of insomnia in all age and sex groups. Individually, 101 of the 109 subjects (92.7%) were above one standard deviation over the normal age and sex group means for this variable.

It is possible that the arousals in these subjects are due to some underlying disturbance that may be identified by sleep recordings. When standard sleep recording procedures have been expanded to include measures of respiration and leg movements it has been found that in certain patients with complaints of chronic insomnia, respiratory pauses (32) or leg movements (38) were associated with nocturnal arousals. In both of these syndromes the disturbance (apnea or leg movements) was completely unknown to the patients until revealed by laboratory sleep recordings. Whether or not these patients should have been excluded from this report remains open to question. Solely on the basis of complaint, there was no reason to exclude them because they were virtually indistinguishable from the 122 subjects reported on here. Parenthetically, objective data show that total nightly sleep times in sleep apnea and nocturnal myoclonus patients are generally somewhat lower than data for the subjects in this report. It also seems clear that similar subgroupings may exist within the 122 subjects, although they are as yet undifferentiated.

What determines the complaint of insomnia? Very few of the subjects in our sample had spectacularly low sleep times, and only 27 averaged less than 5.5 hours per night. Studies involving restricted sleep in normal subjects (44, 45) have shown that reduction of sleep to 5.5 hours a night, even for prolonged periods, does not severely affect mood or performance. Thus one would not expect that sleep loss by itself would lead to the complaints of fatigue, sleepiness, irritability, and impaired performance commonly reported by insomniac patients. The reason such complaints are associated with insomnia and not with being normal but on a restricted sleep schedule may stem from differences in how the sleep loss occurs. That is, normal sub-

jects simply restrict their time in bed, but insomniac patients have striking elevations in the number of arousals. Thus one might speculate that the impairment of daytime activities in people who complain of insomnia is not a result of sleep loss per se but is due to chronic interruptions of sleep. Indeed, in summarizing the relationship of sleep stages to waking behavior, Johnson (46) concluded that "during sleep, the disruption of the REM-NREM cycle may be more relevant to waking behavior than the total amount of wakefulness or time spent in specific sleep stages."

Psychological factors. The MMPI data for our subjects are somewhat different from those obtained by other researchers of insomniac patients (47, 48). We found abnormal profiles in only 58% of our subjects; Kales and Kales (47) found abnormal elevations in 85% and Roth and Kramer (48) in 88% of their patients. In our subjects who had abnormal MMPIs, we found, as did Roth and Kramer, that the neurotic tetrad of depression, hypochondriasis, and hysteria comprised the greatest proportion of abnormal values. It is not clear at the present time why the MMPI results were different in our subjects. Preliminary evaluation, however, showed no relationship between MMPI data and recorded or estimated sleep values.

Psychological evaluation of patients who complain of insomnia is unquestionably important and should be pursued. At the present time, however, we cannot say that chronic insomnia invariably causes depression, anxiety, or other psychological symptoms or that these psychological disturbances cause the complaint of chronic insomnia. At best, we can say that in certain patients psychological disturbance and the complaint of insomnia coexist. Clarifying the relationships of both psychological and physiological disturbances to the complaint of insomnia will be vital in advancing our understanding of this ubiquitous complaint.

The Treatment of Pathological Panic States with Propranolol

BY JON F. HEISER, M.D., AND DON DEFRANCISCO, M.D.

The authors report on the effects of propranolol, a beta-adrenergic blocking agent, on 10 patients with pathological panic states. Propranolol was effective in treating acute pathological panic, but modest doses of the drug administered for brief periods of time did not alleviate chronic panic attacks associated with agoraphobia. The drug suppressed panic associated with depressive syndromes but did not affect the depression and had no clear effect on anticipatory anxiety. The authors suggest that further study of these findings may clarify other clinical problems.

PANIC IS A NORMAL, innate reaction pattern. The adaptive purpose of panic is to promote escape or rapid dispersal. Panic behavior is asocial, and the escape or dispersal may be uncharacteristic, irresponsible, and potentially violent in an impersonal way. The deepest psychobiological and social relationships can be suspended in panic-stricken people: mothers may abandon their infants, soldiers may desert their assignments and buddies, and people may trample relatives and strangers alike. These dramatic and unique features suggest that panic is qualitatively as well as quantitatively different from other forms of fear and anxiety (1). Panic behavior may be maladaptive when rapid dispersal is inhibited or when the stimulus that elicits panic behavior seems inadequate. What happened during the famous Cocoanut Grove fire that took the lives of 491 people in Boston, Mass., in November 1942 is an example of blocked dispersal familiar to behavioral scientists (1, 2). Front-page news stories provide numerous other examples daily.

This paper is concerned only with situations in which the stimulus that evokes panic behavior seems inadequate, i.e., pathological panic states. Modern study of pathological panic states probably began in 1870, when Benedikt termed the condition *platzschwindel* (3). However, with rare exceptions, such as studies of agoraphobia and homosexual panic (3; 4, pp. 1788–1789), the concept of panic, normal or otherwise, has received little attention in psychiatry and psychology.

Interest in the diagnosis and treatment of pathological panic attacks or panic anxiety has increased recently. Preliminary drafts of the proposed third edition of APA's *Diagnostic and Statistical Manual of Mental Disorders (DSM-III)* will probably include a new category, "panic disorder" (5). The increased interest in panic is in large part due to studies that have refined from phobic states a phobic anxiety syndrome with panic attacks (6–10). Klein and associates (8–10) found that tricyclic antidepressants blocked panic attacks (subjective panic accompanied by massive sympathetic and parasympathetic nervous system discharge and considered by these authors the hallmark of the phobic anxiety syndrome) but did not affect anticipatory anxiety (a qualitatively different and less intense anxiety that is generally not associated with more than moderate sympathetic activity but is often associated with elaborate patterns of avoidance and other phobic behaviors). Neither major nor minor tranquilizers are effective in treating panic attacks, but either may decrease anticipatory anxiety (8–10).

The tricyclic antidepressants frequently block panic attacks within hours of the initiation of therapy, in sharp distinction to the 1–3-week delay that patients with retarded (but not agitated) depression often experience before responding to tricyclic antidepressants. Klein and Davis (8) stated that patients with the phobic anxiety syndrome suffer primarily from cardiorespiratory symptoms. Several years ago Lowenstein (11) noted that propranolol was effective in treating agoraphobic patients. He stated that beta blocking agents "reduce to some extent the somatic symptoms of anxiety . . . and often to a marked degree those, e.g., tachycardia and palpitations, related to respiratory alkalosis." Aware that tricyclics may be, among other things, beta blockers (12, 13), we hypothesized that beta-adrenergic blockade was the mechanism by which the tricyclics are effective in the phobic anxiety syndrome.

Dr. Heiser is Assistant Adjunct Professor and Dr. DeFrancisco is Assistant Clinical Professor, Department of Psychiatry and Human Behavior, California College of Medicine, University of California, Irvine, Calif. Dr. Heiser is also Assistant Chief, Adult Psychiatric Inpatient and Emergency Services, and Dr. DeFrancisco is also Chief, Psychosomatic Consultation Service, University of California, Irvine, Medical Center, 101 City Drive South, Orange, Calif. 92668. Address reprint requests to Dr. Heiser at the University of California, Irvine, Medical Center.

The authors thank Drs. John P. Gambin, Irving L. Gislason, Donald E. Watson, and Alan G. Robertson for assistance in referring and treating patients and Dr. John C. Kramer, who made many helpful suggestions.

CASE REPORTS

Results of clinical experience treating 10 patients with propranolol are summarized in table 1. Informed consent was obtained from all of the patients after the nature of all procedures involved in the study was fully explained.[1] Symptom patterns shown by the patients were grouped into four classifications: acute panic attacks with agoraphobia, anxiety states without panic attacks, chronic pain attacks, and depression with panic attacks or severe agitation.

Acute Panic Attacks

Patients with panic states of recent onset obtained immediate beneficial results when given propranolol.

Case 1. This 26-year-old man with three children complained of severe panic that had been occurring sporadically for the preceding 6 months. Each attack lasted several days to 2 weeks and was accompanied by palpitations, weakness, dizziness, a feeling of suffocation, and a fear of dying. He had had similar anxiety attacks in high school. Three years before we saw him he had experienced increasingly severe panic attacks during all of his flights in the Navy and had received a medical discharge because of "flying phobia."

Results of an exhaustive medical evaluation were normal, and 10 mg of diazepam 3 times a day gave no relief. Thirty-six hours after the onset of a panic attack, 10 mg of propranolol was given orally. The patient's symptoms abated within an hour. On a dosage of 10 mg of propranolol 3 times a day his panic states recurred shortly before each dose. Gradually increasing each dose to 20 mg was accompanied by a complete remission. The patient has subsequently experienced no anxiety attacks and has taken his first plane rides since his discharge from the Navy, including a round-trip coast-to-coast flight. He has continued in psychotherapy and has recently been in marital therapy, partly because of what has been interpreted as his wife's difficulty in accepting his decreasing dependency.

Chronic Panic Attacks with Agoraphobia

Patients with chronic phobic anxiety syndromes or agoraphobia received no benefit from brief trials with small doses of propranolol. Two patients immediately developed a phobia to propranolol and discontinued it. One had a dramatic positive response to imipramine. Our prediction that all patients with pathological panic states would be improved when treated with propranolol was therefore not supported.

Case 4. This 27-year-old divorced man was referred because of severe agoraphobia that had slowly progressed over a 5-year period to the point where he was almost completely homebound. Until the unexplained onset of his phobic condition he had been an excellent student and a successful representative for his union in a large aerospace corporation. He now lived alone, had no friends, and was frequently overcome with panic the few times he ventured outside (only when absolutely necessary). His panic attacks were inconsistent and unpredictable and could occur at home. During the attacks he felt palpitations, weakness, dizziness, and a sensation of suffocating. His chronic obsession about dying became a terrifying fear that he would die in the next moment of a heart attack. He twice became addicted to sedatives in attempts at self-medication.

The patient was terrified of the 30- to 40-minute drive to our clinic; he stopped every few blocks to collect himself. He therefore showed up several hours late for his first two appointments and was not seen by the physician. In the habit of taking his pulse frequently, he became extremely concerned after his initial dose of 10 mg of propranolol (prescribed 3 times a day) when he observed that his pulse decreased from 72 to 65 beats a minute. He became more concerned when his heart rate did not abruptly increase following this observation. Caught in a vicious cycle, he became terrified and came to a medical emergency room by ambulance. His pulse still remained normal. After this he considered 5 mg of propranolol a day intolerable because of the changes he noted in his heart rate.

He was given a prescription for 25 mg of imipramine 4 times a day, but, extremely phobic of medication at this point, he took none for 2 weeks. When he finally and reluctantly tried imipramine he felt vastly improved within 24 hours. He discovered himself spontaneously whistling and felt a general sense of well-being for the first time in 5 years. Within a few days he felt free to leave his house as he pleased. With reassurance he became involved in group therapy and began looking for a job.

Anxiety States Without Panic Attacks

Preliminary experience suggests that propranolol provides good results only in patients who have the subjective experience of panic or extreme terror. Free-floating anxiety, depression, and other affects are not altered by the drug.

Depression with Panic Attacks

Treatment with propranolol was associated with elimination of agitation and panic states associated with various types of depression without altering depressive affect or other symptoms of the depressive syndromes.

DISCUSSION

Range of Effectiveness

Although intermittently recommended as psychopharmacological agents for a decade, beta-adrenergic blocking agents have been sparsely evaluated and seen to have only sporadic success in treating various anxiety syndromes. Occasionally they have proven more effective than placebo, particularly in patients with somatic signs of anxiety. They are not generally more effective than minor tranquilizers (17–26). Reports of effective treatment of psychoses (27), alcoholic withdrawal (28), heroin antagonism (29), or other psychiatric conditions (30) with propranolol have not been widely confirmed and remain controversial (31, 32). Jefferson (33) reviewed the status of beta-adrenergic blocking agents in psychiatry in 1974.

The varied response of some psychiatric and medical conditions to beta-adrenergic blockers may be ex-

[1]Propranolol has not been approved by the Food and Drug Administration for the treatment of any psychiatric illness.

TABLE 1
Summary of Case Reports of 10 Patients Treated with Propranolol

Item	Age (years)	Sex	Marital Status	Chief Complaint	Diagnosis	Previous Medications	Current Medications
Group 1: acute panic attacks							
Case 1	26	Male	Married	Severe panic for 6 months	Phobic neurosis (phobic character)	No response to diazepam	No panic after 20 mg of propranolol 3 times a day started
Case 2	26	Male	Married	Severe panic for 6 months	Anxiety neurosis	No response to diazepam	No panic after 10 mg of propranolol 4 times a day started
Case 3	24	Female	Separated	Tachycardia and depersonalization of recent onset	Anxiety neurosis	Unknown	No panic after 10 mg of propranolol 2 times a day started
Group 2: chronic panic attacks with agoraphobia							
Case 4	27	Male	Divorced	Progressive agoraphobia with panic attacks for 5 years	Phobic neurosis (agoraphobia)	Addicted to sedatives twice	Phobic response to first dose of 10 mg of propranolol 3 times a day; prompt and complete remission with imipramine
Case 5	44	Female	Married	Progressive agoraphobia with panic attacks for 17 years	Phobic neurosis (agoraphobia)	Modest temporary improvement, worsening, or no response with various medications	Phobic response to 10 mg of propranolol 3 times a day for 2 days; further treatment rejected by patient
Case 6	39	Female	Married	Progressive agoraphobia with panic attacks for 7 years	Phobic neurosis (agoraphobia)	Modest improvement with hormone injections, diphenylhydantoin, and diazepam	No benefit but side effects with 2-week trials of 20 mg of propranolol 4 times a day, imipramine, propantheline, and phenelzine; temporary remission with regressive ECT
Group 3: anxiety states without panic attacks							
Case 7	21	Male	Single	Feeling weird and feeling mind blank	Anxiety neurosis	None recorded; possible untoward reaction to LSD	No benefit from brief trials of 10 mg of propranolol 4 times a day, thiothixene, doxepin, and amitriptyline; euphoria during sodium amytal interview; improvement with diazepam
Group 4: depression with panic attacks or severe agitation							
Case 8	48	Male	Married	Hyperventilation syndrome with panic attacks and phobias	Involutional melancholia	Modest improvement with propranolol and diazepam prescribed by internist	10 mg of propranolol 3–4 times a day blocked panic attacks but left affect and vegetative signs of depression untouched; severe weakness with 25 mg of amitriptyline 3 times a day; modest improvement with a maximum dose of 20 mg of doxepin a day

TABLE 1 (continued)
Summary of Case Reports of 10 Patients Treated with Propranolol

Item	Age (years)	Sex	Marital Status	Chief Complaint	Diagnosis	Previous Medications	Current Medications
Group 4							
Case 9	56	Female	Married	Recurrent psychotic depression	Involutional melancholia or recurrent psychotic depression	Fair response to combination of phenothiazine and tricyclic antidepressant	Agitation and tremors responded to 10 mg of propranolol 3 times a day; depression responded to thioridazine and imipramine; severe depression no longer occurred with lithium and occasional imipramine*
Case 10	30	Male	Single	Severe suicide attempts because of chronic severe depression and "flushing attacks" accompanied by weakness, dizziness, rage, and a vague anxiety	Psychotic depressive reaction, recurrent psychotic depression, melancholic personality, or anaclitic depression	Unknown	"Flushing attacks" stopped with 20 mg of propranolol 3 times a day; depression not affected by propranolol; depression improved and flushing diminished with imipramine and occasional thioridazine; patient committed suicide after discharge from another hospital**

*Whether the agitation and tremor were primary symptoms of this patient's depression or side effects of amitriptyline or thioridazine is not certain. Pitts (14) used propranolol to combat tricyclic-antidepressant-induced tremor and considered tricyclic antidepressants beta-adrenergic activators.
**The subjective affect of this patient's "flushing attacks" was composed of rage and a vague anxiety, not panic. Treatment with an alpha-adrenergic blocking agent might be effective in such cases (15, 16).

plained if a distinction is made between panic states, which seem to be promptly blocked by propranolol, tricyclic antidepressants, and monamine oxidase (MAO) inhibitors (34, 35), and other types of anxiety, which do not respond consistently or dramatically to propranolol. Chronic episodes of panic and agoraphobia may represent gradual developments and/or end stages of acute panic attacks or may be clinically distinct entities.

No one has explained why reactive or neurotic depressions, which appear clinically distinct from endogenous or psychotic depressions, may respond, albeit sporadically, to tricyclic antidepressants. At least some reactive depressions may respond to beta-adrenergic blockade when symptoms are exacerbated by an underlying panic state (36). This may also help explain the prompt response of patients with agitated depression to antidepressants and/or phenothiazines (8).

Whether patients who consult cardiologists because they have various forms of the hyperdynamic heart syndrome (37) or neurologists because of familial, senile, or essential tremors (38, 39) are different from patients complaining to psychiatrists of panic attacks is unknown. Frohlich and associates (37) found that during an infusion test with the beta-adrenergic stimulating agent isoproterenol 9 of 14 patients with a "hyperdynamic beta-adrenergic circulatory state" displayed "an hysterical outburst, almost uncontrollable" that was promptly reversed by intravenous propranolol but not by placebo. Conversely, anxious individuals with normal or slightly increased heart rates before isoproterenol had a normal heart-rate response to infusion of isoproterenol and did not exhibit dramatic emotional outbursts.

Propranolol is used in the treatment of cardiac arrhythmias, hyperthyroidism, hypertropic aortic stenosis, and angina pectoris. It is also used with alpha-adrenergic receptor blocking agents in preparing patients with pheochromocytoma for surgery (40, 41). Although not approved for such use by the Food and Drug Administration, propranolol has also been used for hypertension, hyperthyroid crises, migraine headaches, and certain neurological tremors (38, 39, 42, 43). It has been reported (44) that the tricyclic antidepressant amitriptyline was effective in preventing severe migraine headaches, apparently independent of an antidepressant effect.

Thirty years ago Ficarra and Nelson (45) reported that phobias may be the presenting complaint in patients with hyperthyroidism. The differential diagnosis of patients with acute panic attacks, agoraphobia, and lesser forms of fear and anxiety must include these conditions and other organic dysfunctions such as paroxysmal atrial tachycardia. It is important to determine whether such patients have a specific physiological disorder that should be treated rather than just receive medication to control their symptoms.

The long-term psychological impact of blocking a homeostatic response is unknown. Our preliminary experience and literature review suggest substantial changes only in persons with pathological panic attacks that serve no apparent vital or useful function. We have no example of the reaction of a propranolol-treated patient in a situation in which panic (with escape or rapid dispersal) might be adaptive.

Mechanism of Action

The mechanism of action of propranolol in treating psychiatric symptoms is also unknown. Propranolol might act through the central or peripheral nervous systems. Propranolol has pharmacological effects other than beta-adrenergic blockade, including membrane-stabilizing activity (quinidine-like or local anesthetic action) with large doses and a sedative and anticonvulsant effect on the central nervous system that is apparently unrelated to beta-adrenergic blockade. It has almost no beta-adrenergic activating effects, although some are present in other beta-adrenergic blockers such as practolol. Any combination of these properties and placebo effects could have affected our patients. Whether propranolol relieves mental and physical suffering or merely reduces somatic manifestations of agitation and anxiety is unknown.

A fortuitous combination of beta-adrenergic blockade (or stimulation), alpha-adrenergic blockade, anticholinergic and sedative properties, stimulation of catecholamine- and serotonin-mediated systems, and regulation (rather than blockade or stimulation) of any of these phenomena and other unspecified properties may make the tricyclics effective or more acceptable in the treatment of agoraphobia (46, p. 199; 47, 48).

Tyrer and associates (35) postulated that the favorable response of phobic patients to MAO inhibitors is unlikely to be due to their antidepressant effect because in their studies care was taken to exclude depressed patients and improvement correlated negatively with the initial depression rating. The mechanism of action of MAO inhibitors against phobic symptoms is unknown, but MAO inhibitors also block the autonomic nervous system (48).

Pharmacokinetics

The optimal dose range, the duration of treatment, and the long-term effects of propranolol when used for psychiatric conditions are not known. Klein's group (8–10) stressed the pattern of exacerbation and remission of the phobic anxiety syndrome and suggested that intermittent therapy may suffice or be preferable. Suzman (21) reported anxiety-relieving responses to as little as 40 mg of propranolol a day. Most of his patients responded to 160 mg a day, but some required 320 mg a day temporarily. Many patients were followed between several months and 6 years without evidence of untoward reactions. Gardos and associates (31) found that effective beta-adrenergic blockade occurred at doses of 180 mg a day, and increasing doses did not increase blockade. In treating schizophrenic and manic-depressive patients, Atsmon and associates (27) reported beneficial effects from daily doses of 1000 to 5000 mg of propranolol. These large doses and ranges suggest the possibility of different mechanisms or sites of action.

Shand and associates (49) reported that peak plasma levels in 5 subjects varied sevenfold following oral administration of propranolol. Plasma levels after intravenous administration in the same subjects varied twofold. Plasma levels were relatively constant when subjects were given the same dose more than once. Plasma levels reached a maximum 1½ to 2 hours after an oral dose was taken while the subject was fasting and after 2 to 4 hours when the dose was taken with a meal. The plasma half-life was 3.2 hours when taken orally and 2.3 hours after intravenous administration.

Future Prospects

As already noted, propranolol has not been approved by the Food and Drug Administration for the treatment of any psychiatric disorder. Although we do not recommend general application of our findings at this time, further studies may clarify the clinical applications and the mechanism of action of propranolol. Such studies should point toward the classification, etiology, natural history, pathophysiology, and clinical psychopharmacology of pathological panic states, the phobic anxiety syndrome, agoraphobia, the hyperventilation syndrome, homosexual panic, psychocardiac disorders, some types of affective disorders, pseudoneurotic and latent schizophrenia, borderline syndromes and personality disorders (3–11, 17–39, 43, 44, 50, 51). Studies also need to be made of the relationships of these traditionally psychiatric conditions to such medical conditions as the hyperdynamic heart syndrome, migraine headaches, and familial, senile, or essential tremors. Adding terms such as "pathological panic state" or "pathological extreme terror state" and qualifying them as propranolol sensitive or propranolol resistant may prove useful to work in this area.

Delinquency, Psychomotor Epileptic Symptoms, and Paranoid Ideation: A Triad

BY DOROTHY OTNOW LEWIS, M.D.

In a retrospective chart-review study, the author found psychomotor epileptic symptoms in 6% (N=18) of children referred to a juvenile court over a 2-year period. Abnormalities appeared in 11 of the 14 available EEGs, but temporal lobe foci were noted in only 3 cases. Of these 18 children, 16 experienced paranoid symptoms that led to aggressive behavior. The incidence of offenses against persons was 50% in this sample, compared to 2–3% in the population of children referred to the juvenile court. The author suggests that psychomotor epilepsy may be far more common among delinquent children than has been reported previously and should therefore be included in the differential diagnosis of court-referred children.

THE PURPOSE of this paper is to report a high prevalence of psychomotor epileptic symptoms coupled with paranoid ideation and behavior in a group of children referred to a child psychiatry clinic in a juvenile court setting. (I have deliberately used the term "symptoms" because discrete abnormal EEG foci were not always documented.) I will also discuss the central nervous system dysfunction of these children in relation to birth histories, medical histories, EEG findings, and the nature of the offenses that brought them to the court's attention.

As Ervin has pointed out, "No doubt there exist as many definitions of epilepsy as there are neurologists and as many types of epilepsy as there are patients" (1, p. 1138). Nevertheless, there is some consensus regarding the symptomatology of so-called "psychomotor-temporal lobe" seizure states (2–4). The criteria I have used for psychomotor epileptic symptoms are similar to those of Rutter and associates (5). Each child demonstrated or had a clear history of at least four of the following symptoms: auras of anxiety or fear, a variety of visceral symptoms, alterations in consciousness (usually without complete loss of consciousness), complex thought processes and feeling states, automatic behaviors, and auditory, visual, and sensory hallucinations. There was partial amnesia for the manifestations of the seizure states, but the total amnesia so characteristic of grand mal epilepsy was not always present. In many cases there was a complex interplay of physiologically and psychologically or environmentally induced behaviors that sometimes made it difficult to tell that a seizure was in progress or had taken place.

Although symptoms were associated with discrete temporal lobe EEG foci of abnormality in some children, they also occurred in children with normal or diffusely abnormal EEGs. The EEGs of children suffering from psychomotor epilepsy often demonstrate diffuse abnormalities (5). Glaser and Dixon (6) have pointed out that discrete temporal lobe foci of abnormal electrical discharge are more characteristic of adult psychomotor epileptics than juvenile psychomotor epileptics and that "focal temporal spikes are relatively infrequent (10%) and are elicited in only slightly higher incidence in sleep." Consequently the EEG was not a major criterion for the diagnosis. That normal encephalograms are sometimes found in psychomotor epilepsy may be attributed to the fact that EEGs are often obtained between actual seizures or that the seizure focus is deep in the brain, within the limbic system, and therefore inaccessible to ordinary EEG techniques (7). Although there have been investigations of psychomotor epileptic symptoms in neurological patients, psychiatric patients, and prisoners, little work has been done on the prevalence and characteristics of the disorder in delinquents.

This study consisted of a retrospective review of the charts of every child with psychomotor epileptic symptoms referred to a juvenile court clinic over a two-year period. Data were gleaned from psychiatric, psychological, medical, and (when available) EEG records.

CLINICAL FINDINGS

Of 285 children referred to the clinic during the two-year study period, 18 (6%) either described or demonstrated in the course of interviews symptoms consistent with a diagnosis of psychomotor epilepsy. This prevalence is many times that of all forms of epilepsy, which has been estimated to occur in .3–.4% of the population. Psychomotor epilepsy is thought to be between a third and a sixth as common as grand mal epilepsy (1, 2, 8). Thus, the finding that 6% of the clinic-referred delinquents manifested psychomotor epileptic symptoms is noteworthy.

Episodes of loss of fully conscious contact with real-

Dr. Lewis is Associate Clinical Professor of Psychiatry, Child Study Center, Yale University, 333 Cedar St., New Haven, Conn. 06510.

ity were characteristic of all 18 children. These altered states of consciousness lasted from several seconds to several hours and occasionally occurred during psychiatric interviewing, medical examination, or psychological testing. In many cases this symptom took the form of "blackouts," long staring episodes, or falling. In several cases the behavior was complex and seemingly purposeful, as was true of 3 children who wandered away from their homes. Two were found wandering the streets, oblivious to their surroundings, and the third came to her senses after wandering through a park, walking across a shallow pond, and winding up in an unfamiliar part of town without knowing how she got there.

It was often difficult to assess the timing of certain behaviors in relationship to seizures and to know which behaviors were auras, which occurred during a seizure, and which occurred following a seizure. One child described "a funny feeling something is going to happen" just prior to episodes of loss of awareness. Others gave histories of dizziness, nausea, and visual distortions that could not always be related temporally to subsequent documented seizures. Only 4 children had histories of the automatisms often associated with psychomotor seizures. Two had histories of lip smacking or mouth movements, and 2 had histories of more complicated but nevertheless stereotyped behaviors during which they were not conscious of their surroundings and could not understand what was said to them. Four children experienced frequent episodes of déjà-vu. Many of the children tried to explain their experiences to themselves; one child concluded, "I must have ESP."

Eight children complained of frequent severe headaches, and 7 reported dizziness and/or nausea that sometimes accompanied the headaches. One child commented, "It feels so bad I throw up."

Nine children had experienced hallucinations: 4 reported visual hallucinations only, 2 auditory hallucinations only, and 3 both auditory and visual hallucinations. One child with visual hallucinations also reported feeling the house tilt. Usually the hallucinations had a neutral quality; 4 children said they frequently heard their names called or heard voices in another room. However, 2 children experienced extremely threatening, frightening auditory hallucinations; 1 girl heard a voice say, "I'll kick her butt," and a boy heard the words, "Get him!"

It was of special interest to find that 16 of these 18 children also experienced paranoid symptomatology in the form of delusions. These delusions ranged from feeling whispered about and picked on or persecuted by friends and teachers to a child's conviction that he/she was being stalked by a murderer. Several children described feelings of being about to be attacked. "I try to hurt someone before they hurt me," a young man explained. Five children frequently carried weapons. One boy explained that he "had to get them before they get me." Four other children had histories of picking up heavy objects such as wrenches and chairs and flinging them at others without observable provocation. Thus most of the children with psychomotor epileptic symptoms had actually behaved aggressively in response to feelings of being threatened or attacked.

One of the most frequent manifestations of aggressiveness was frequent fighting at school in response to imagined threats. Teachers had observed these children lashing out at other children with no apparent provocation and then, with conviction, accusing the other children of starting the conflict. Some children were aware that they were unable to stop fighting once a fight began. One boy explained, "I can't stop myself. Somebody else takes control." Three children described strong wishes and even attempts to kill playmates or siblings, 2 children had histories of torturing animals, and 2 children actually did kill schoolmates.

ELECTROENCEPHALOGRAPHIC FINDINGS

Information from waking EEGs was available or obtainable in 14 of the 18 cases. In the 4 other cases circumstances made it impossible to obtain EEGs. Furthermore, although it would have been desirable to obtain sleep EEGs, the special staffing required for this kind of procedure was rarely available in the court setting. It was also not possible to obtain nasopharyngeal leads. Of the 14 EEG reports available, 11 indicated an abnormality or a possible abnormality, but a temporal lobe focus was evident in only a few cases—only 3 of the 11 abnormal reports mentioned focal temporal lobe abnormalities. One report mentioned an abnormal rhythm in the right anterior temporal lobe, 1 a focus of slow-wave activity in the left temporal lobe as well as generalized slowing, and 1, slowing in both temporal areas, more prominent on the left. Of the 3 children with temporal lobe foci, 2 had violent histories. The most common EEG report was of generalized slowing or nonspecific or diffuse abnormalities. Four reports mentioned occasional sharp waves or bursts in addition to generalized slowing.

MEDICAL HISTORIES

A striking finding was a history of serious trauma to the central nervous system in 15 of the 18 children. Three children had been hit by cars, lost consciousness, and were hospitalized. Seven children had experienced other kinds of serious head trauma, including falling from a tree and being hit in the head with a baseball bat (which necessitated surgery). Two children had had other kinds of seizures earlier in childhood: one had grand mal seizures associated with fevers and another had Jacksonian seizures associated with head trauma. One child had had Guillain-Barré syndrome. One child was reported to have been moribund in infancy from a disease of unknown characteristics.

Six of the 18 children had histories of definite per-

inatal trauma, including prematurity, prolonged labor, maternal hypothyroidism, maternal toxemia, and maternal syphilis. One child was delivered following physical assault on the mother. Six of the children were known to have occasionally used alcohol to excess, but only one was known to have committed a violent act after drinking, thereby conforming to Mark and Ervin's (7) description of "episodic dyscontrol." Only 2 children had perfectly normal perinatal and medical histories; one of them had a strong family history for epilepsy of other kinds. Five of the 18 children had close relatives with known epilepsy.

TYPES OF OFFENSES

A major question is whether the symptoms described bore a special relationship to the kinds of offenses for which a child was referred to court. Children's offenses were classified in terms of severity: minor "status" offenses, such as truancy, running away from home, and incorrigibility; offenses against property, such as theft, breaking and entering, and malicious mischief; and offenses against persons, i.e., assault and murder. Of the 18 children with psychomotor epileptic symptoms, 13 had committed minor offenses, 9 had committed property offenses, and 8 had committed offenses against persons, 2 of which were murders. (Several children in the group had committed more than one kind of offense.) Of note was the finding that offenses against persons were committed by nearly half of the children in this group, whereas offenses against persons constitute only about 2-3% of the offenses for which children are referred to this particular court. Six of the children who were referred ostensibly for "status" or property offenses had actually attacked other individuals in school or at home but were charged with less serious offenses. Thus 14 of the 18 children had histories of seriously aggressive behavior.

DISCUSSION

In this sample of 18 children with psychomotor epileptic symptoms, the disorder was frequently associated with aggressive behaviors and offenses against persons. The literature on psychomotor epilepsy is filled with debate about whether or not this disorder is associated with aggressive acts.

Some authors have stressed the abnormal personalities and/or "interictal states" of individuals who periodically demonstrate the more common symptoms of the seizure itself (3, 4, 9–11). Some papers have called attention to an association of violent or antisocial behaviors with psychomotor epilepsy (6, 9, 12, 13), but others have questioned this relationship (14–18). Wilson and Harris (18) studied 39 psychomotor epileptic children and found aggression and outbursts of anger to be rare phenomena. Loomis (19) failed to find a significant association between EEG abnormalities, specifically temporal lobe abnormalities, and behavior disorders in delinquents. Rodin (14) reported no instance of aggressive behavior during or after induced seizures in epileptics and also found that temporal lobe foci were no more common in aggressive than in nonaggressive epileptics. Gunn and Bonn (16) found no difference in violence between epileptic and nonepileptic prisoners.

On the other hand, Glaser and Dixon (6) found fear and anger associated with severe aggressive behavior in many psychomotor epileptic children. Ounsted (12) also reported an association of episodic aggressive behavior and psychomotor or temporal lobe epilepsy. Serafetinides (13) also found aggressiveness to be especially characteristic when seizures commenced before the age of 10, and Treffert (9) found "assaults, black-outs, and rage episodes" to be more frequent among individuals with temporal lobe epilepsy than psychotic nonepileptic patients.

Much of the disagreement regarding the association of violent behaviors and epilepsy arises from the difficulty involved in ascertaining which behaviors are part of a seizure itself and which occur between obvious seizure episodes. Several investigators have stressed the complex nature of the aggressive behavior of some psychomotor epileptics and have asserted that such behavior could not be part of a seizure or postictal state (15, 20).

In this study, the aggressive behaviors of children with psychomotor epileptic symptoms, while reported to occur occasionally during altered states of consciousness, usually seemed to occur between seizure manifestations and were most frequently committed in response to a child's perceived, or rather misperceived, sense of being threatened. Children with psychomotor epileptic symptoms complained of being picked on, followed, or even assaulted, when to the outside observer this was not the case. Offenses were often associated with these kinds of paranoid feelings. Some so-called "runaways" wandered off at night, feeling pursued by nonexistent enemies. Some children termed "incorrigible" attacked others as a result of misperceptions. One child actually killed another when she mistakenly thought a knife was being pointed at her.

What is the source of these paranoid feelings? Feelings of fear and anxiety are known often to precede psychomotor seizures. Furthermore, psychomotor epileptics often experience what Glaser and associates (4) referred to as "a waxing and waning of alertness and fluctuation in the accuracy of perceptions." Such fluctuating awareness was seen during the course of psychiatric, medical, and psychological evaluations of this sample. Auditory and visual misperceptions also occurred. It is easy to understand how an individual whose world is frequently changing, unpredictable, threatening, and anxiety-provoking might develop paranoid ideation and behavior. Several investigators have mentioned, almost in passing, that psychomotor

epileptics often have, among other symptoms, paranoid ideas as well as hallucinations (4, 9, 20–22). As early as 1951, Gibbs (3) hypothesized that pathophysiological disturbances in the brain lead to disturbances of perception, evaluation, and judgment. Taylor (23) conceptualized the association between aggressiveness and epilepsy as one of impaired learning that at times showed itself in aggressive behavior. Defensiveness might thereby be seen as a reaction to changing, frightening perceptions and misperceptions.

Most of the children in this sample had received serious central nervous system injuries early in life. Following this, they experienced changing states of awareness, episodes of intense anxiety or premonitions of danger, and learning difficulties. It is likely that these factors, over the course of time, contributed to the paranoid outlook of 16 of the 18 children with psychomotor epileptic symptoms. Often a paranoid misperception coupled, perhaps, with impaired impulse control, led to the offenses that brought the children to the attention of the juvenile court. Violence was more common in the psychomotor epileptic children evaluated than in other children referred to court. This violence, however, was rarely thought to be associated with an actual seizure state, but rather with the paranoid outlook the seizure disorder engendered.

The finding of a high prevalence of psychomotor epileptic symptoms coupled with paranoid symptoms in a population of delinquent children suggests that psychomotor epilepsy is probably more common among delinquents than has previously been recognized and that it should be part of the differential diagnosis of court-referred children.

Effects of Legal Pressure on Prognosis for Treatment of Drug Dependence

BY ROBERT J. HARFORD, PH.D., JAMES C. UNGERER, M.A., AND J. KEVIN KINSELLA, ED.D., M.P.H.

The authors found that four measures of legal pressure were either unrelated or negatively related to retention and outcome in five drug abuse treatment modalities. This suggests that nonvolunteer clients are likely to be insufficiently motivated to benefit fully from treatment and their presence may adversely affect staff morale and prognosis of volunteer clients. The authors recommend that legal pressure not be used as a basis for assigning applicants to treatment modalities and suggest that treatment outcome might be improved by procedures that 1) deal clinically with motivational differences between volunteers and nonvolunteers, 2) establish stricter motivational criteria for admitting nonvolunteers, or 3) encourage enforcement of existing sanctions against violations of stipulations to treatment.

THE RELATIONSHIP between drug abuse treatment agencies and the criminal justice system has been the subject of much discussion and of several articles in the drug abuse treatment literature. These reports, buttressed by a wealth of anecdotal evidence, have supported three related beliefs that have been cited to promote cooperation between treatment personnel and law enforcement authorities.

The first of these beliefs is that arrest and vigorous prosecution of persons who use illegal drugs prevent the spread of drug abuse. According to this hypothesis, enforcement of legal restrictions against unprescribed drug use is the most potent form of primary prevention and a necessary adjunct to treatment efforts (1). However, published studies of attempts to validate this proposition are scarce.

The second belief is that treatment for addiction reduces the criminal activities of drug abusers. This view is based on the premise that addicts commit criminal acts at least in part to finance their drug use. Successful treatment reduces their dependence upon illegal drugs and therefore their need to commit crimes. Several investigations have demonstrated that criminal activity of individuals in drug abuse treatment programs seems to decrease during and after treatment (2–5). Still undetermined is the extent to which these decreases in criminal activity are attributable to the effects of treatment (6, 7), or can be explained in terms of biased self-reports of criminal activities (8), differential mortality, maturation effects, or a statistical regression artifact.

The third belief, which is the main focus of this report, hypothesizes that legal pressure on addicts facilitates their treatment for addiction. Looney and Metcalf (9), for example, have distinguished between internal and external pressures that lead drug abusers to seek treatment. Based on their clinical experience, they concluded that internal motivation is "worth little unless augmented by other kinds of pressure." For drug abusers above the age of 18, the external motivation is usually legal pressure. Looney and Metcalf concluded that "no addict successfully seeks treatment for his addiction without the stimulus of strong external pressure."

Although many drug abuse treatment authorities would endorse these assertions, the literature on this important question is inconclusive (10). It suggests that a weak positive relationship between legal pressure and treatment outcome may exist but could be attributable to other factors, such as the positive relationship between legal pressure and age. The relationship may also depend on the type of legal pressure and the type of treatment.

This report describes the relationships among four measures of legal pressure and treatment retention and completion rates in five treatment modalities. The analyses tested the hypothesis that legal pressure is positively related to retention when the effects of age are controlled by statistical techniques.

METHOD

Facilities

The Drug Dependence Unit (DDU), New Haven, Conn., a multimodality addiction rehabilitation facil-

Based on a paper presented at the Second National Drug Abuse Conference, New Orleans, La., April 2–6, 1975.

The authors are with Yale University School of Medicine, where Dr. Harford is Assistant Professor of Psychiatry, Mr. Ungerer is Clinical Instructor in Psychiatry, and Dr. Kinsella is Assistant Professor of Psychiatry. Dr. Harford is also Director, Research and Program Evaluation, Drug Dependence Unit, Connecticut Mental Health Center, 100 Park St., New Haven, Conn. 06511.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grants DA-01097 and DA-16356 from the National Institute on Drug Abuse, Herbert D. Kleber, M.D., Principal Investigator.

ity, has been described in detail by Kinsella and associates (11). The five DDU treatment programs we studied are Alpha House, a residential program for adolescents; Daytop, a residential therapeutic community for young adults; Veritas House, a day program for adolescents; Low Intervention Program (LIP), an outpatient abstinence and narcotic antagonist program that primarily serves young adults; and Methadone, a program for opiate abusers over the age of 21.

Population

During the period from January 1, 1971, to December 31, 1973, 1,083 persons applied for treatment at the DDU for the first time. More than half (N=619) did not enter treatment. Of those who did enter treatment, the distribution among the programs was as follows: Daytop, N=131; Methadone, N=113; Alpha House, N=36; Veritas House, N=66; LIP, N=58; and other treatment programs, N=60. This study analyzed the relationships among legal pressure at the time of application and rates of retention and treatment completion for the 404 members of the five DDU treatment modalities through June 30, 1975.

Measures

Legal pressure was defined to exist if the applicant reported being on probation, on parole, or awaiting trial at the time of application. The fourth measure of legal pressure was a logical composite of these three legal pressure statuses. Clinicians monitored client participation in treatment by sending weekly program status reports to the research unit.

RESULTS

Applicant Group Characteristics

The 404 applicants who were admitted for treatment (37.3%) were significantly older than the 619 who were not admitted (means=23.1 and 21.9 years, respectively, $p<.001$, t test). Applicants who were on parole were significantly more likely to enter treatment than those who were not on parole (48.4% versus 36.3%, $p<.05$, chi-square test) but those who were on probation or awaiting trial were no more likely to be admitted to treatment programs than those who were not on probation or who had no cases pending. The composite measure of legal pressure (either on parole, on probation, or with litigation pending) showed that applicants with at least one type of legal pressure were significantly more likely to be admitted than applicants with no legal pressure (40.1% versus 33.7%, $p<.05$, chi-square test). Distributions by sex, race, and principal drug of abuse did not differ between those admitted and those not admitted to treatment.

Admissions Group Characteristics

Table 1 summarizes the characteristics of clients admitted to the five treatment programs. The programs differed significantly in the percentages of clients who were on probation, on parole, or had legal cases pending. The differences were greatest for the composite measure of legal pressure. Table 1 also shows that probation and pending litigation were about equally frequent as sources of legal pressure (33.9% and 34.9%, respectively), while only 10.9% of the total admissions were on parole at the time of their application for treatment. The five programs did not differ significantly in sexual or racial composition, but clients admitted to Methadone were older (mean=27.8 years) than those admitted to LIP (mean=24.1), Daytop (mean=22.1 years), Veritas (mean=19.6), and Alpha (mean=18.6). All programs differed significantly from each other in terms of age with the exception of Alpha and Veritas. As Expected, primary heroin abusers accounted for virtually all admissions to Methadone but for significantly fewer admissions to the other programs.

Legal Pressure and Treatment Outcome

As of June 30, 1975, 212 (52.4%) of the clients had terminated this first treatment episode in bad standing, 29 (7.2%) had been expelled, 5 (1.2%) had been incarcerated as the result of postentry criminal offenses, 39 (9.7%) had been referred to other treatment facilities, 22 (5.4%) terminated against program advice but in good standing, 30 (7.4%) continued as active program members, and 67 (16.6%) had successfully completed treatment. Table 2 presents the percentages of clients with and without legal pressure who graduated. Chi-square analyses were conducted to test the hypothesis that legal pressure at the time of application is associated with successful completion of treatment for addiction. For each of the three types of legal pressure and the composite measure, a 2 × 2 contingency table of Legal Pressure × Treatment Completion Status (graduate versus nongraduate) was constructed for each treatment program. None of the chi-square tests approached the .05 level of significance. These outcome data showed no relationship between treatment completion rates and any of the four measures of legal pressure.

Retention in Treatment

Although legal pressure was not related to successful completion of treatment as defined by graduation, legal pressure may be positively related to retention for the majority of clients who did not meet the rather stringent criteria for graduation. If the benefits of treatment are positively correlated with retention, then legal pressure might facilitate treatment even though it does not influence the rate of successful completion. To test this possibility, a series of four two-way analyses of variance was performed on the retention times of all nongraduates. The two independent variables were program (5 levels) and pressure (2 levels). The pressure variable was alternately probation status parole status, pending litigation status, or the composite measure of legal pressure. The results showed a substantial Program main effect but no main effect or inter-

action involving any of the four measures of legal pressure. The cell means for these analyses, displayed in table 3, indicate that 15 of the 20 comparisons showed greater mean retention for the group not under legal pressure. None of the t tests for these comparisons was statistically significant. Scheffé multiple comparison tests showed that the significant Program main effects were attributable to the much longer mean retention in Methadone compared with the four other clinical programs, which did not differ among themselves.

Significant mean within-programs correlations of age with retention ($r=.172$, $p<.001$), parole status ($r=.162$, $p<.001$), and probation status ($r=-.250$, $p<.001$) indicated that, within programs, 1) older applicants tended to be retained longer than younger applicants, 2) applicants who entered treatment while on parole were older than those not on parole, and 3) applicants who entered treatment while on probation were younger than those not on probation. None of the measures of legal pressure was significantly correlated with retention.

In order to distinguish the possibly confounded effects of age and legal pressure on retention in treatment, the four analyses of variance (ANOVAs) were repeated with age included as a third independent variable. This procedure allowed assessment of the effects of age on retention independently and in interaction with program and pressure. Since age was related to both program and pressure, median splits were performed according to age within each of the Program × Pressure cells of the ANOVA design. Thus, there were two levels of age, above and below the median, which were determined separately for the 10 cells.

The four ANOVA results generally were similar to the results of the Program × Pressure analyses except for a significant main effect for Age, i.e., older applicants were retained longer than younger applicants. In addition, the ANOVA that included probation pro-

duced two significant interactions involving age and probation. Table 4 presents the summary table for this ANOVA. The significant Age main effect resulted from the fact that older applicants remained in treatment longer than younger applicants (247.7 days versus 183.3 days). The significant Age × Probation interaction showed that older applicants who were on probation had a significantly lower mean retention (100.1 days) than older clients who were not on probation (296.1 days). Retention of younger applicants did not differ according to their probation status. The second-order Age × Probation × Program interaction indicated that the Age × Probation interaction was obtained primarily in the Alpha and Methadone programs. These two interactions reflect the only significant effects of legal pressure on treatment progress. They indicate that older applicants who entered Alpha and Methadone while on probation were likely to terminate treatment earlier than either older applicants who were not on probation or younger applicants regardless of their probation status. This finding contradicts the major hypothesis that legal pressure facilitates treatment for addiction.

DISCUSSION

The principal finding of this study was that older Methadone and Alpha House clients who were admitted for treatment while on probation were retained for shorter periods of time than clients who were not on probation. No other differences in retention or graduation rates involving any of the four measures of legal pressure were statistically significant. This finding indicates that older clients on probation were greater risks for early attrition in Methadone and Alpha House. It also suggests the possibility that legal pressure inhibits rather than facilitates treatment for addiction.

Why should differences in retention of clients on probation be related to age? One explanation might be that older clients in these programs are more aware that leaving treatment is not considered a serious violation of the conditions of their probation. Once they have escaped the immediate threat of incarceration, older clients may prefer risking further action from probation officers to participating in a rigorous treatment regimen. For whatever reasons, the consequences of violating probation were not generally effective in motivating retention in treatment.

The high attrition rates in drug abuse treatment pro grams suggest that clients need to be highly motivated to change their life-styles before treatment can be effective. The greater the external compulsion toward the goal of abstinence, the less the clients need to modify their beliefs, attitudes, and motivations in pursuit of this goal. The nonvoluntary client can always persuade himself that he is participating in treatment activities primarily to avoid incarceration. He may be more likely than the internally motivated volunteer to remain passively alienated from treatment activities and to avoid accepting personal responsibility for treatment outcome.

The failure of involuntary clients to develop commitments to treatment goals may adversely affect the morale of treatment staff and dilute the quality of treatment delivered to volunteer clients. Perpich and associates (12), for example, reported that criminal justice referrals were arrested more often during treatment and were more likely to continue illicit drug use than volunteers. Since involuntary clients outnumber volunteers 2 to 1 and are more difficult to treat, they often receive a disproportionate share of clinical attention. The predominance of nonvolunteers also contributes to the development of program procedures and regulations emphasizing the social control aspects of rehabilitation, which is less than optimal therapy for volunteers. These factors reduce the probability of successful treatment of volunteers.

The prognosis for volunteers might be enhanced by establishing more stringent motivational criteria for admission of nonvolunteers to treatment programs. At present, any type of legal pressure is viewed as a positive indication of treatment success. The results of this study, along with those of Perpich and associates, indicate that just the opposite is true. Applicants who are referred by the criminal justice system should be screened especially carefully for signs of intrinsic motivation toward abstinence and commitment to the treatment regimen. Nonvolunteers who do not meet the motivational criteria could receive inpatient treatment with increased motivation for abstinence as the goal.

Outcomes of treatment for nonvolunteers might be improved by stricter supervision and closer liaison with the referring agencies of the criminal justice system. Many of these referrals believe that dropping out of treatment will not jeopardize their legal status. A policy of vigorous enforcement of existing penalties for violating the conditions of parole or probation would make it more difficult for the nonvolunteers to leave before treatment is completed.

Although legal pressure motivated many of these clients to apply for treatment, there is no evidence that it improved their graduation or retention rates. Legal sanctions against unprescribed drug use, therefore, should not be justified on the grounds that they increase the probability of successful treatment. Furthermore, since clients with legal pressure did no better than those without legal pressure in any of the programs, legal pressure should not be used as a criterion for assigning applicants to specific treatment modalities.

CONCLUSIONS

Our results suggest that, during a time when legal pressure on drug users seems to be increasing, there is no evidence to demonstrate its effectiveness in facilitating their rehabilitation. This indicates the need for more definitive research on the effects of withdrawing legal pressure, types of legal pressure, enforcement of legal pressure, and various program ideologies within types of treatment. Future research also should consider measures of rehabilitative success other than retention. The proposition that legal pressure facilitates treatment for addiction is a causal assertion, and its verification requires experimental procedures with random assignment to conditions. Correlational approaches cannot provide sufficient evidence for causal relationships between legal pressure and treatment outcome.

Our findings merely suggest that legal pressure does not enhance the probability of successful rehabilitation. Clients under legal pressure might not have been retained as long if they had not been obliged to enter treatment. This possibility could be tested either by assigning legal pressure at random to clients prior to their entry into treatment or by withdrawing legal pressure at random from clients after they have entered treatment. In either case, differences in treatment outcome could be attributed to the presence or absence of legal pressure.

Definitive information on this issue is desirable from a humanitarian point of view, because legal pressure may be more dysfunctional than drug abuse. Without good empirical evidence that it benefits the individual or society either by decreasing drug abuse incidence rates or increasing the efficacy of treatment, continued support of legal pressure for drug-related offenses may perpetuate a misdirection of diminishing treatment resources.

Journal Policy on Multiple Authorship

It has come to our attention that there has been some misunderstanding regarding the *Journal's* policy on polyauthorship. The number of authors listed on a paper is not a factor in the review and acceptance/rejection procedure. However, once a decision has been made to publish a paper, we do apply *Journal* policy regarding the number of authors in the by-line: only principal researchers and writers of articles are listed in the by-line; collaborators who have provided technical and other assistance are acknowledged in a footnote. In papers that list more than 4 people as principal authors, we query the first author to verify that those individuals were substantial contributors to the research or ideas reported. Since certain types of psychiatric research may require multiple workers, we will of course include all of the names in these cases.

Routine On-Line Psychiatric Diagnosis by Computer

BY JOHN H. GREIST, M.D., MARJORIE H. KLEIN, PH.D., AND HAROLD P. ERDMAN, M.S.

With the advent of effective psychiatric treatments, greater accuracy in psychiatric diagnosis has become a vital concern for psychiatric training, research, and patient care. The authors have adapted current computer diagnostic procedures in order to obtain highly accurate diagnoses while simplifying and shortening the process of information input and diagnostic output. Their program requires a minimum of the clinician's time and provides feedback during the diagnostic process when the clinician requires it. The authors believe that routine use of this computer diagnostic program will improve psychiatric training, research, and patient care.

SINCE THERE ARE now different and effective treatments for various psychiatric disorders, accurate diagnosis is no longer an intellectual exercise or simply a research requirement. When one is dealing with psychiatric patients, especially acutely psychotic patients, it is important to identify early in treatment disorders that are likely to respond to specific treatments.

In clinical settings, particularly, clinicians need help with psychiatric diagnosis. Many studies have shown a relatively low reliability between clinicians' diagnoses of the same patient (1–3). Clearly, most clinicians are not able to remember and obtain diagnostically relevant data, organize and retain diagnostic logic, eliminate their biases, and use diagnostic labels in the ways they were intended. In contrast to this experience, high diagnostic reliability has been reported by research groups using standardized diagnostic criteria and decision-making procedures (4–7).

Recognizing the problems inherent in the psychiatric diagnostic process (as well as the lack of objective measures analogous to the pathognomonic constellations of laboratory tests and tissue biopsies that are available in most of medical practice), several workers (8–12) have attempted to harness the computer's unquestionable reliability to improve psychiatric diagnosis. Spitzer and Endicott have made a sustained effort in this field, and their work deserves special comment. They have evolved 3 diagnostic programs, DIAGNO I (13), DIAGNO II (14), and DIAGNO III (15, 16), all of which use data obtained from clinician-completed forms. Because mental status data were found to be sufficient for diagnosis by the program (at least for newly admitted patients), more detailed historical material was deleted from the diagnostic algorithm. Output was in the form of 79 psychiatric diagnoses listed in the American Psychiatric Association's *DSM-II* (17).

In one study (15) comparing DIAGNO III diagnoses with diagnoses made by an "expert" diagnostician and a psychiatric resident or psychology intern who performed a detailed initial evaluation of 100 consecutively admitted psychiatric patients, agreement between the computer and the admitting clinician's diagnoses was as good as that between diagnoses of the admitting clinician and the expert diagnostician; in 65 cases there was complete agreement. In 20 of the 35 cases where there was disagreement the computer diagnosis would have aided the clinician, but it would have been misleading in the remaining 15 cases. In these 15 cases 9 diagnoses were invalid because of "specific ratings made by the therapist on the forms which did not seem justified or even likely." For the remaining 6 invalid diagnoses the authors found that the "computer algorithm was insensitive to a clinical distinction that both the therapist and the senior author were able to make" (p. 527). Poor quality input data and insensitivity of diagnostic algorithms appear to be the major problems with computer-assisted diagnosis in psychiatry. Clinicians find repetitive completion of a standardized form to be so boring that they may become careless. Part of this attitude results from the lack of timely and meaningful feedback from these computer programs.

Spitzer and Endicott (15) reported that the inadequacies of the diagnostic algorithm were partly attributable to the

> ambiquity in the definition of many of the categories of the official nomenclature. For several cases, the ambiguity in distinguishing between psychotic and nonpsychotic conditions resulted in disagreements in diagnosis that would be difficult to resolve between any two experienced clinicians who followed the less than precise recommendations of *DSM-II*. (p. 529)

The authors are with the Department of Psychiatry, University of Wisconsin Medical School, 1300 University Ave., Madison, Wis. 53706, where Dr. Greist and Dr. Klein are Associate Professors and Mr. Erdman is Project Coordinator.

This work was supported in part by Alcohol, Drug Abuse, and Mental Health Administration grants MH-22030, MH-25546, and Research Scientist Development Award MH-70903 from the National Institute of Mental Health, grant DA-00903 from the National Institute on Drug Abuse, and by the Foundations' Fund for Research in Psychiatry, New Haven, Conn.

Spitzer and Endicott commented that the use of "more precise definitions of psychiatric disorders, such as those that have been recently proposed by the group at the Washington University School of Medicine at St. Louis [4], would undoubtedly avoid some of these problems" (p. 529). *DSM-III*, which is scheduled to appear in 1978, will emphasize more specific operational criteria than its predecessors did (18).

NEW DIAGNOSTIC CRITERIA

The collaborative program on the psychobiology of depressive disorders sponsored by the Clinical Research Branch of the National Institute of Mental Health (NIMH) has developed Research Diagnostic Criteria (*RDC*) (19) that are derived in large part from the work done at the Renard Hospital (Washington University, St. Louis). Although the primary focus of the NIMH study is depression, it has been necessary to differentiate depressed patients from those with other affective disorders, thought disorders, neuroses, personality disorders, and alcohol and other drug-abuse problems.

One problem with the *RDC* as presently constituted is their complexity, which becomes clear when they are applied. For example, to make a diagnosis of "mania" the clinician must satisfy the following 5 specific criteria: 1) elevated or irritable mood; 2) 3 of 7 manic symptoms if mood is elevated and 4 if mood is only irritable; 3) illness duration of more than 1 week or hospitalization required; 4) impairment of meaningful conversation or impaired social, family, or occupational functioning; and 5) exclusion of schizophrenia. The specificity and complexity of the criteria give this approach its considerable predictive power, but it is this same specificity and complexity that make it difficult for clinicians to use the *RDC* efficiently in routine clinical settings.

ON-LINE DIAGNOSIS

In order to make the diagnostic procedure easy to use we have turned to interactive computing techniques (20). As an initial step in the development of a computer consultation program we have adapted *RDC* procedures so that the clinician can directly and quickly obtain research diagnoses for patients he or she is seeing.[1] The clinician interacts directly with a computer terminal by reading questions or statements on a television screen and responds by pressing keys (usually a single number) on a typewriter keyboard (see figure 1). The decision-making process involves the use of branching logic between questions that is contingent upon the clinician's responses, as well as code written in the MIIS computer language to speed up the process. In this way, the number of questions presented to the clinician by the computer terminal is kept to a minimum and completion time for the program (which includes 25 diagnoses) is between 10 and 15 minutes.

FIGURE 1
Illustration of the Interaction Between Physician and Computer in On-Line Psychiatric Diagnosis

Information gathered during the interview is stored in variables, e.g., counting the number of manic or depressive symptoms present, and at decision-making points these can be tested to see if the criteria for a particular diagnosis have been met. At any point that a diagnosis can either be definitely confirmed or rejected, further questions relevant to that diagnosis are terminated. Decisions made on previous diagnoses are also stored in 1 variable that is checked when making diagnoses that are mutually exclusive. A physician-computer dialogue is illustrated in appendix 1.

DISCUSSION

This approach to collecting data and the capacity of the computer to keep track of and weigh the criteria until they are sufficient (or insufficient) for a diagnosis make the *RDC* applicable for routine clinical use. Twenty-five diagnoses are presently included in the computer program. When fully developed, this approach will be a great improvement over "computerized" diagnostic procedures available in the past. In earlier systems the clinician had to administer a complex structured interview and record answers in a complicated mark-sense format (i.e., he or she made marks in specific boxes on a form and the marks were sensed by an optical scanning device) just to obtain information that could be computer processed. Further delays in data entry, as well as time involved in running computer programs and reporting results to the clinician, made this process lengthy and cumbersome (15, 16).

[1]A Digital Equipment Corporation PDP-15 supporting MIIS software is used for this work. At present there are more than 50 compatible systems in the United States supporting more than 1,200 independent users. Other systems are located in Germany, France, and Brazil.

Our program is constructed to use the *RDC* in a way that will make the diagnostic process highly accurate, requiring a minimum of the clinician's time, with feedback during the diagnostic process when the clinician requires it. In effect, the program uses the substance of the *RDC* exactly as it was intended, but considerably simplifies and shortens the process of information input and diagnostic output so that the clinician can routinely use the program to obtain research-quality diagnoses. More than 30 clinicians have used the program in a preliminary trial and, with 1 exception, felt that the diagnoses they received were accurate and helpful. Most users described patients who had presented difficult diagnostic problems and were often surprised that the computer's diagnosis agreed with their own.

Based on our experience with other medical and psychiatric consultation programs, clinicians' use of this program will alert them to information needed for accurate diagnosis and will sharpen their interviewing and diagnostic skills even when they are not using the program. Computer consultation programs of this kind appear to be a very effective teaching device since they are employed at the time that clinicians need to learn specific information to solve a clinical problem.

The diagnostic program can include sample cases representing a range of diagnostic problems. Clinicians can "work up" these cases, with the computer providing prompt feedback on the effectiveness and efficiency of their approach. These sample or test cases can serve as one measure of the diagnostician's skill, and cases can be added to emphasize new developments in the field of diagnosis. When this case workup approach is integrated with the summary diagnostic statements that clinicians receive regarding specific patients they describe (see the last frame of appendix 1), it provides a new level of immediacy and authenticity in teaching psychiatric diagnosis.

Continual updating of the clinician's program will be necessary as new diagnostic information becomes available. For example, a recently reported (21) association between EEG patterns and bipolar affective disorder could be incorporated into the program if it is found to hold up in replication studies. Other data from longitudinal case studies, verified descriptions of symptoms and signs, laboratory tests, family histories, and empirical records of response to treatment will be included as they are found to be diagnostically useful.

Deficiencies of earlier programs more typically resulted from the poor quality of data available for processing than from fundamental weaknesses in the diagnostic algorithms employed. Investigations are under way to evaluate what effects the use of branching for data collection and immediate diagnostic feedback will have on the clinician's use of the program. Using the standardized and complete data collected by the program, we are also beginning to study the accuracy of diagnoses obtained, with the intention of improving the diagnostic algorithm when possible.

While the clinician's version of the program is being tested, we are also developing a parallel version to collect information directly from the patient (when feasible) and, using the same diagnostic decision process developed for the clinician program, to provide diagnoses to be verified by the clinician.

With the advent of effective psychiatric treatments, greater accuracy in psychiatric diagnosis has become a vital concern for psychiatric training, research, and patient care. Routine use of this computer diagnostic program can have an impact on each of these areas.

APPENDIX 1
A Model Physician-Computer Dialogue for On-Line Psychiatric Diagnosis

HOW LONG HAS THE PRESENT EPISODE BEEN OCCURRING?

1. LESS THAN 2 DAYS
2. 2 TO 7 DAYS
3. 8 TO 14 DAYS
4. 15 TO 30 DAYS
5. 31 DAYS TO 3 MONTHS
6. 3 MONTHS TO 2 YEARS
7. MORE THAN 2 YEARS

PHYSICIAN'S ANSWER: #4

HAS THE PATIENT BEEN HOSPITALIZED FOR TREATMENT OF THIS EPISODE OF ILLNESS?

1. YES
2. NO
3. DON'T KNOW

PHYSICIAN'S ANSWER: #2

TYPE NUMBERS THAT CORRESPOND TO SYMPTOMS OR SIGNS YOUR PATIENT HAS.

1. THOUGHT BROADCASTING, INSERTION, OR WITHDRAWAL
2. DELUSIONS OF CONTROL, OTHER BIZARRE OR MULTIPLE DELUSIONS
3. DELUSIONS OTHER THAN PERSECUTORY OR JEALOUSY
4. DELUSIONS WITH HALLUCINATIONS
5. AUDITORY HALLUCINATIONS
6. NONAFFECTIVE VERBAL HALLUCINATIONS
7. DEFINITE INSTANCES OF FORMAL THOUGHT DISORDER
8. CATATONIC MOTOR BEHAVIOR
9. NONE OF THE ABOVE

PHYSICIAN'S ANSWER (MORE THAN 1 O.K.): #9

TYPE NUMBERS THAT CORRESPOND TO SYMPTOMS OR SIGNS YOUR PATIENT HAS.

1. MORE ACTIVE OR RESTLESS THAN USUAL (AT WORK, SOCIALLY, OR SEXUALLY)
2. MORE TALKATIVE THAN USUAL OR FELT A PRESSURE TO TALK ON
3. FLIGHT OF IDEAS OR RACING THOUGHTS
4. INFLATED SELF-ESTEEM
5. DECREASED NEED FOR SLEEP
6. DISTRACTIBILITY
7. EXCESSIVE INVOLVEMENT IN ACTIVITIES WITH A HIGH POTENTIAL FOR PAINFUL CONSEQUENCES
8. NONE OF THE ABOVE

PHYSICIAN'S ANSWER (MORE THAN 1 O.K.): #1, 2, 3, 5, 7

TYPE NUMBERS THAT CORRESPOND TO SYMPTOMS OR SIGNS YOUR PATIENT HAS.

1. WEIGHT CHANGE (GAIN OR LOSS OF 1 LB/WEEK OVER SEVERAL WEEKS OR 10 LBS/YEAR WHEN NOT DIETING)
2. INSOMNIA OR HYPERSOMNIA
3. LOSS OF ENERGY, TIRED, OR FATIGUED
4. PSYCHOMOTOR AGITATION OR RETARDATION
5. LOSS OF INTEREST OR PLEASURE IN USUAL ACTIVITIES (INCLUDING SEX)
6. SELF-REPROACH OR INAPPROPRIATE GUILT
7. COMPLAINTS OR EVIDENCE OF DIMINISHED ABILITY TO THINK OR CONCENTRATE
8. THOUGHTS OF DEATH OR SUICIDE
9. NONE OF THE ABOVE

PHYSICIAN'S ANSWER (MORE THAN 1 O.K.): #1

HAS YOUR PATIENT HAD ONE OR MORE DISTINCT PERIODS OF PREDOMINANTLY ELEVATED OR IRRITABLE MOOD? (MOOD CHANGES SHOULD BE A RELATIVELY PERSISTENT OR PROMINENT PART OF THE ILLNESS, OR OCCUR FREQUENTLY, BUT MAY ALTERNATE WITH A DEPRESSED MOOD. IF ALCOHOL OR OTHER DRUG INTAKE HAS BEEN GREAT ENOUGH TO AFFECT MOOD, ANSWER NO).

1. MOOD ELEVATED
2. MOOD IRRITABLE
3. MOOD ELEVATED AND IRRITABLE
4. NONE OF THE ABOVE

PHYSICIAN'S ANSWER: #3

HAS YOUR PATIENT SOUGHT HELP FROM SOMEONE DURING THIS EPISODE OF ILLNESS OR HAD IMPAIRED FUNCTIONING SOCIALLY, WITH FAMILY, AT HOME, OR AT WORK?

1. YES
2. NO

PHYSICIAN'S ANSWER: #1

DIAGNOSIS* MANIA*
RDC WERE:

A. DURATION 15 TO 30 DAYS (>1 WK. OR HOSP. REQUIRED)
B. 5 MANIC SYMPTOMS (3 REQ. IF MOOD ELEVATED, 4 IF IRRITABLE)
C. MOOD ELEVATED AND IRRITABLE
D. SEVERITY (HOSP. OR CONVERSATION IMPOSSIBLE OR SOCIAL, HOME, OR WORK IMPAIRMENT)
E. 0 SCHIZOPHRENIC SYMPTOMS (1 ALLOWED)

REVIEW MANIA RDC IN GREATER DETAIL?

1. YES
2. NO

PHYSICIAN'S ANSWER: #2

The Effect of Lithium on Impulsive Aggressive Behavior in Man

BY MICHAEL H. SHEARD, M.D., JAMES L. MARINI, PH.D., CAROLYN I. BRIDGES, M.A., AND ERNEST WAGNER, M.D.

The authors conducted a double-blind, placebo-controlled study of the effect of lithium on aggressive behavior. The 66 subjects, who were prisoners in a medium security institution, ranged in age from 16 to 24 years, were physically healthy and nonpsychotic, and had histories of chronic impulsive aggressive behavior. Subjects received lithium or placebo daily for up to 3 months. There was a significant reduction in aggressive behavior in the lithium group as measured by a decrease in infractions involving violence. The authors suggest that lithium can have a clinically useful effect upon impulsive aggressive behavior when this behavior is not associated with psychosis.

PRELIMINARY REPORTS (1–4) have suggested that lithium exerts an inhibiting effect on chronic human aggressive behavior and therefore might be useful in the treatment of some forms of pathological aggressiveness in man. The previous work, however, consisted of single-blind (1–3) or nonblind (4) studies, and confirmation of these reports, as well as development of treatment criteria, requires further research using double-blind procedures. The study we will describe was a three-year double-blind evaluation of the effect of lithium on the aggressive behavior of incarcerated delinquent males with histories of chronic impulsive aggressive behavior.

Dr. Sheard is Associate Professor of Clinical Psychiatry and Dr. Marini is Research Associate, Department of Psychiatry and Connecticut Mental Health Center, Yale University School of Medicine, 34 Park St., New Haven, Conn. 06508, where Ms. Bridges was Research Assistant and Dr. Wagner was Assistant Clinical Professor of Psychiatry when this work was done. Dr. Wagner is now in private practice.

This study was supported by Alcohol, Drug Abuse, and Mental Health Administration grant MH-21934 from the National Institute of Mental Health.

The authors would like to thank the inmates and staff of the Correctional Institution, Cheshire, Conn., especially Mr. James Teel, for their cooperation, and Mr. Josh Auerbach for statistical consultation.

Slow-release lithium (Priadel) was supplied by Delandale Laboratories, Canterbury, England. Rowell Laboratories, Inc., Baudette, Mich., provided placebo.

METHOD

Subjects

The subjects were male inmates aged 16-24 at the medium security Correctional Institution at Cheshire, Conn. The criteria used for subject selection were 1) conviction for serious aggressive crimes (e.g., manslaughter, murder, rape, assault) plus a history of chronic assaultive behavior and/or a history of chronic impulsive antisocial behavior, 2) freedom from psychosis, 3) good physical health with no renal, cardiac, or organic brain disease, 4) ability to comprehend the written material used in the study, 5) sentence of sufficient duration to ensure time for completion of the study, and 6) termination of any psychoactive medication with consent of the prescribing physician.

Subjects were referred by the institution's counseling staff, who had been given a detailed description of the study. A subject's suitability was determined by the staff psychiatrist (E.W.) and the senior investigator (M.H.S.). The selected subjects were then presented with a detailed oral explanation of the study, including purpose, risks, and possible benefits. After a 1–2 week waiting period they were asked if they were willing to participate. Those who agreed were required to sign a consent form. Identical consent forms signed by parents or guardians were required for subjects under 18.

Of a total of 159 referrals, 101 subjects were judged suitable and agreed to participate. A total of 80 remained in the study long enough to receive medication. Of these, 14 dropped out of the study or were transferred, giving a sample of 66 individuals. Mean ages (±SD) were 19.4±1.76 years for lithium subjects and 19.5±1.49 years for placebo subjects.

Procedure

Subjects were paid $3.75 a week for their participation whether or not they completed the experiment, and those who did finish or whose termination was beyond their control (e.g., transfer to another institution) received a bonus of $2.50 a week. Thus the total pay was $6.25 a week, for a maximum of $125.00 for 5 months, which is equivalent to the monthly remuneration for the best paying inmate jobs at the institution. Throughout the study, the subjects continued their normal routines aside from the 1–2 hours each week when they performed study tasks and evaluations. They re-

ceived no special privileges or amenities within the institution.

Initial evaluations. All subjects received a standard physical workup and mental status evaluation. Data on personal history were obtained, as well as information on brain damage (Memory-For-Designs Test [5]). IQ was measured by the Peabody Picture Vocabulary Test (6) and, in some cases, the Raven Progressive Matrices Test (7). The Lykken Sociopathy Scale (8) was also administered. In addition, all subjects received an initial evaluation battery consisting of the Minnesota Multiphasic Personality Inventory (9), the Rotter I-E Scale (10), the Eysenck Personality Inventory (11), The Buss-Durkee Hostility Inventory (12), the Adjective Check List (13), and the Personality Research Form (14).

Experimental design. The 5-month experimental protocol began with 1 medication-free month that served as a control period. During the next 3 months subjects were given once-daily doses of either sustained-release lithium carbonate (Priadel) or an identical-appearing placebo. The fifth month was again drug-free. Placebo contained sodium carbonate, sodium bicarbonate, and dicalcium phosphate dihydrate in a ratio of 2:3:4.

Subjects were randomly assigned to lithium or placebo by the senior investigator or a laboratory research assistant, with the constraint that the groups not differ in number by more than 3 subjects at any given time. The study staff—a psychopharmacologist (J.L.M.), a psychologist (C.I.B.), and a psychiatrist (E.W.)—were blind to medication assignment, as were all of the personnel at the institution. Lithium and placebo were packed in identical capsules, and each subject received 5 capsules once a day. Serum lithium levels were assayed weekly and adjusted when necessary by altering the amount of lithium within the 5 capsules. Thus, placebo subjects took 5 capsules containing placebo daily and the lithium subjects took 5 capsules containing placebo and varying amounts of lithium. The goal was to maintain 24-hour serum lithium levels in the range of 0.6–1.0 mEq/liter. Subjects also completed a weekly 24-item symptom checklist, which included 7 lithium "target symptoms": shakiness or hand tremor, drowsiness, nausea, vomiting, polyuria, anorexia, and diarrhea.

Assessment of change. Four measures were used to evaluate changes in behavior or attitude during the study.

1. The number of infractions of institutional rules committed by the subjects was determined from reports routinely issued by the institutional staff, who were blind to the medication received. In this institution, infractions are defined as major ("reports") and minor ("tickets"). Major infractions consist of serious threatening behavior or actual assaults and result in loss of privileges and, frequently, time in the "hole" (segregation unit). Minor infractions are less serious offenses such as possession of contraband or being out of place and usually are punished by loss of recreational privileges. The number of infractions was compared in two ways: 1) comparisons for all subjects for equal periods before, during, and after medication, and 2) month-by-month comparisons throughout the study.

2. A test battery consisting of the Multiple Affect Adjective Check List (15), Arrow-Dot Test (16), Common Annoyances Test (17), and the Rosenzweig Picture Frustration Test (18) was administered each month.

3. The tests used in the initial evaluation battery were repeated during the final drug-free month at least 2 weeks after the final dose of medication.

4. Behavior rating scales were completed by the authors weekly.

Statistical analysis. The data were analyzed by means of Student's t-test, chi-square tests, analyses of variance and covariance, and linear discriminant function analysis.

RESULTS

Of the 66 subjects, 34 received lithium for periods of 3 months (N=20), 2 months (N=8) or 1 month (N=6), and 32 received placebo for 3 months (N=21), 2 months (N=9), or 1 month (N=2).

Personality, Psychological, and Demographic Data

There were significantly more black subjects in the placebo than in the lithium group (53.1% versus 20.6%, $p<.01$), and the significant difference in IQ shown in table 1 is due to a significant racial difference on the vocabulary-based IQ test we used. This difference was not found when the nonverbal Raven Progressive Matrices Test was used as a measure of IQ.

TABLE 1
Results of Initial Battery of Psychological and Personality Tests

Test	Lithium Group (N=34) Mean	Lithium Group (N=34) SD	Placebo Group (N=32) Mean	Placebo Group (N=32) SD
MMPI				
Psychopathic deviance scale	78.4	9.9	77.2	6.3
Manic scale	81.0	8.0	79.7	10.5
Eysenck Personality Inventory				
Neuroticism	12.9	4.6	13.0	4.5
Extraversion	13.9	3.6	13.7	4.5
Rotter I-E Scale	12.1	3.3	11.5	2.7
Lykken Sociopathy Scale	17.2	4.1	16.8	3.7
Buss-Durkee Hostility Inventory				
Total	29.2	6.9	31.7	6.4
Physical	8.09	1.59	8.21	1.10
IQ (Peabody Picture Vocabulary Test)*	93.0	15.9	83.9	10.0

*Lithium group significantly higher than placebo group ($p<.01$).

The very high scores on the Rotter I-E Test indicate that the subjects in both groups feel that controls stem from outside themselves, and high Lykken scores indicate a lack of anxiety and high risk-taking preference. A very high percentage of subjects in both groups came from broken homes, had lost a parent before the age of 16, or had been adopted or placed in foster homes. Antisocial behavior before the age of 12 was common in this group and continued from the ages of 12 to 18. Eighty to ninety percent of the subjects had been incarcerated for 1 or more years between the ages of 12 and 18, and there were comparable percentages of reports of significant fighting under the age of 12 and between the ages of 12 and 18. This was an extremely manipulative, hostile, and aggressive group of young men who were extroverted, highly impulsive, and action oriented. The MMPI, while not highly reliable with this type of subject, showed the usual peaking on the psychopathic deviate and manic scales. Various test scales measuring hostility showed extremely high scores. In general, the subjects can be classified as having nonpsychotic personality disorders.

Serum Lithium Levels

Twenty-four hour serum lithium levels and the average dose for each week on medication are shown in table 2.

Infractions

Table 3 shows that the lithium group had significantly fewer major infractions and fewer total infractions while on the medication than the placebo group. Minor infractions showed a tendency to increase during the medication period for both placebo and lithium groups.

Figure 1, which illustrates infractions committed from month to month, shows a progressive drop in major infractions for the lithium group. Independent t tests of month-by-month changes show a just significant difference in major infractions for the fourth month ($p=.05$). It is interesting to note that the number of infractions starts to rise again in the fifth month, which was drug-free. Analysis of variance revealed a significant Drug × Monthly Test Interval interaction ($p<.02$), indicating that the progressive decrease in infractions in the lithium-treated group was related to medication regimen. Because of the difference in racial composition of the lithium and placebo groups, an additional analysis of variance was done with this variable added (Drug × Monthly Test Interval × Race). This analysis also showed a significant difference between the groups ($p<.03$), indicating that the statistically significant difference was not due solely to the racial factor. An analysis of covariance using the average major infractions during the premedication period as a covariate approached significance for the third month and was significant for the fourth month ($F[1, 38]=4.34$, $p<.05$) and for the sum of the third and fourth months ($F[1, 36]=5.5$, $p<.05$) of medication.

TABLE 2
Average Weekly Serum Lithium Levels and Dose for Lithium Group

Medication Week	N	Serum Lithium (mEq/liter) Mean	SD	Dose (mg)
1	32	.68	.27	1212
2	31	.64	.20	1229
3	29	.81	.29	1482
4	33	.76	.32	1524
5	29	.77	.30	1563
6	25	.80	.29	1571
7	22	.78	.25	1550
8	24	.77	.28	1541
9	19	.73	.24	1554
10	21	.89	.29	1600
11	20	.89	.13	1652
12	16	.89	.36	1691

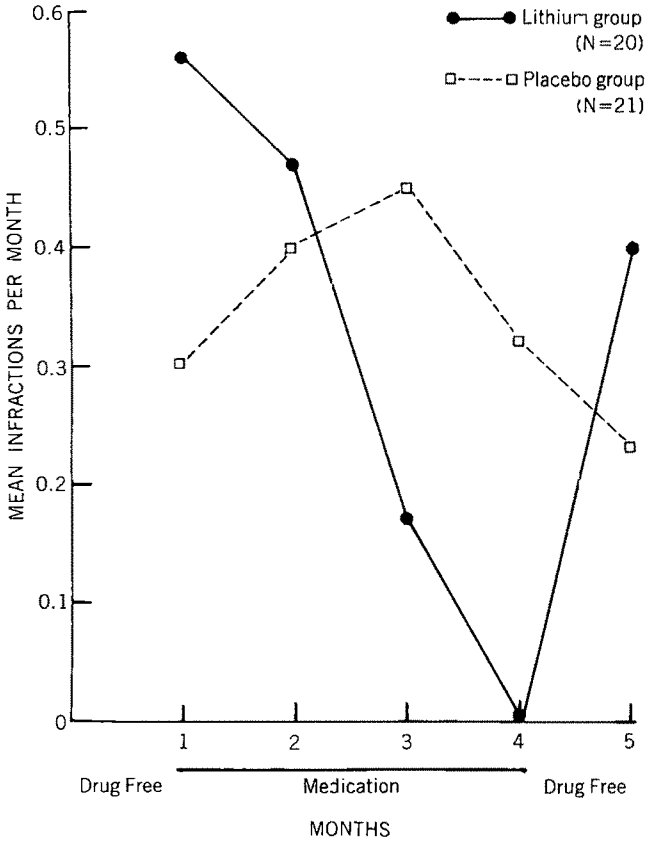

TABLE 3
Total Number of Infractions for Equivalent Periods of Time Before and During Medication

Type of infraction	Placebo Group (N=31) Pre-medication	Placebo Group (N=31) On Medication	Lithium Group (N=28) Pre-medication	Lithium Group (N=28) On Medication
Major	34	32	54	23*
Minor	27	40	29	34
Total	61	72	83	57**

*Significantly different ($p<.01$).
**Significantly different ($p<.05$).

A further analysis of the infraction data revealed that of the 41 subjects who completed 3 medication months, 8 of 20 lithium subjects versus 5 of 21 placebo subjects had no infractions (not significantly different). Of the 17 subjects who completed 2 months, 5 out of 8 in the lithium group and none of the 9 in the placebo group received no infractions ($\chi^2=9.74$, $p<.01$). Of the 8 subjects who completed 1 month, 5 out of 6 lithium and none of 2 placebo subjects had no infractions ($\chi^2=7.98$, $p<.01$). Using each subject as his own control for major infractions, we found a significant difference in the lithium group between predrug infraction scores and medication period infraction scores ($t=3.6$, $p<.01$). There was no significant difference for the placebo group on this comparison. A linear discriminant function analysis was performed using the fourth-month scores of major infractions, the arrow-dot test, the MAACL (hostility subscale only), and the Common Annoyances Test. The infraction scores had the greatest weight, the MAACL hostility score the next greatest, and the arrow-dot test scales had reasonably high weights. The discriminant function was significant for these three tests ($p<.01$) and for the major infractions and MAACL hostility together ($p<.05$).

FIGURE 1
Comparison of Major Infractions per Month for the Lithium and Placebo Groups

Evaluation of the Double-Blind

The success of the double-blind procedure was evaluated by an analysis of guesses of group assignment by staff and subjects (19). The three staff members' guesses did not differ from chance either taken as a group or individually. However, the subjects' guesses as a group did achieve significance ($p<.05$). When the guesses of the lithium and placebo group were analyzed separately, we found that the placebo group did not guess at a better than chance level, whereas the lithium group's guesses were highly significant (80% correct, $p<.01$).

Side Effects

During the 1-month premedication period, the average weekly target symptom scores of the lithium and placebo groups were not significantly different. On medication, however, the lithium subjects reported a significantly higher target symptom score each week of the 3-month drug period ($p<.01$). For the 4 postdrug weeks there was again no significant difference between the two groups. A total of 16 subjects who received medication quit the experiment—14 had received lithium and 2 placebo. The placebo subjects both reported that they quit because they disliked the experiment, but of 11 lithium subjects who dropped out and gave reasons, 10 reported side effects. The side effects reported most frequently were hand tremor or shakiness, dryness of mouth, polyuria, and nausea (20).

DISCUSSION

This study provides further evidence that lithium can have an inhibitory effect on impulsive aggressive behavior as measured by reduction of incidents of such behavior while on the medication. Although the difference in racial composition reduces the comparability of the two groups, the analysis of variance allowing for the racial difference still showed a significant medication effect on major infractions. Moreover, there were few significant differences between the two groups on the psychological tests of the initial evaluation battery despite the racial difference.

Particularly supportive of the antiaggressive effect of lithium is the progressive decline in infractions month-by-month to zero by the fourth month in the lithium group. The fact that minor infractions tended to increase over the same period suggests that lithium did not merely globally inhibit behavior. It should also be pointed out that the lithium group had a greater number of infractions than the placebo group in the predrug period. This difference is accounted for by 5 individuals who had a greater number of infractions in the predrug period than the rest of the subjects. This aggressive behavior occurred over an extended period of time, however, and was not a function of some unusual short-lived episode. Moreover, it biases the lithium group in a direction that would be expected to operate against achieving a significant effect with lithium.

In view of the length of the study, an overall variation in the frequency of major episodes might have led to a skewed distribution. However, an examination of the data did not suggest that this was the case. Moreover, this would be important only if there were some periods during which only lithium or placebo subjects were assigned to the study, which was not the case. Also, it is possible that subjects who finished the course might have had a different pretreatment frequency of major episodes than those who dropped out before being treated. Our data cannot fully answer this question, but a comparison of 31 subjects who finished 11–12 medication weeks with 32 who dropped out before 11 weeks did not reveal a significant difference in predrug major infractions.

The evaluation of the double-blind methodology revealed that the lithium subjects could guess that they had received lithium, presumably from the side effects they experienced (19). Although this means that using lithium and placebo in this fashion cannot be said to be rigorously double-blind, it is also true that lithium subjects did not subjectively experience any more benefit from the medication than did the placebo group, as was shown by a specific questionnaire administered to each subject at the end of his participation (21). Therefore, although they could identify the medication, they

did not feel it was necessarily making a change in their behavior and thus they were not subject to a positive suggestive effect from the medication.

An Interpersonal Approach to Hysteria

BY DAVID CELANI, PH.D.

The author defines hysteria in terms of specific observable classes of interpersonal behaviors and examines the impact of these behaviors on the receiver. The hysteric communicates frailty and helplessness, thus structuring the interpersonal environment to ensure attention and inhibit aggression. The development of these roles is shown in histories of female hysterics, who were selectively reinforced for frailty, seductiveness, and passivity as children. The major classes of symptoms shown by adult hysterics—conversion symptoms and dissociative reactions—reflect these interpersonal roles. The author concludes that hysteria is a relatively specific interpersonal style that results from cultural, social, and interpersonal influences.

IN THE PAST, "hysteria" was defined exclusively by the presence of specific symptoms, defense mechanisms, or dynamics. The publication of Chodoff and Lyons' paper on the behavioral characteristics of hysterics (1) began a trend in which hysteria was perceived as a personality type that was correlated with certain symptoms but essentially independent from them. Other papers that followed used the behavioral diagnosis and focused on descriptive and demographic material (2, 3), somatic disturbances (4), as well as the characteristics of interpersonal (5) and verbal (6) behavior. Despite this trend, there is still a lively debate within the psychodynamic school regarding the oral or phallic origins of the conflict that ultimately produces hysterical behavior (7). This paper is an attempt to present a unified picture of this personality type from the interpersonal-communicational viewpoint.

CLINICAL DESCRIPTION

In females, the most general description of the hysterical interpersonal style is an exaggeration and overplaying of the feminine social role. Chodoff and Lyons' behavioral description of hysteria (1) was abstracted from the existing dynamically oriented literature and accurately portrays the extreme state of this personality type.

Dr. Celani is Instructor, Department of Psychology, University of Vermont, Burlington, Vt. 05401.

> The hysterical personality is a term applicable to persons who are vain and egocentric, who display labile and excitable but shallow affectivity, whose dramatic, attention seeking and histrionic behavior may go to the extremes of lying and even pseudologia phantastica, who are very conscious of sex, sexually provocative yet frigid, and who are dependently demanding in interpersonal situations. (1, p. 736)

Most of these behaviors can be seen at infrequent intervals in nonhysterical women since they are appropriate (in moderation) to the feminine social role; it is possible that they will be seen less as the concepts of women's liberation become part of the culture. It would be difficult if not impossible for a male to qualify as a hysteric if these behavioral characteristics were the absolute arbiters. Males can have hysterical personalities (8) without necessarily conforming to female sex-role behaviors. The problem lies in defining hysteria in terms of specific behaviors without considering the interpersonal purpose or impact of the behaviors.

The most basic assumption in the interpersonal approach is that all behaviors of individuals in interactions represent attempts to produce in the other person an emotional state that will tend to elicit a predictable response (9). A second assumption is that all individuals have a need to keep their behavior in line with their self-perceptions and their perceptions of others. Neurotics are viewed as individuals with faulty self-perceptions that require constant confirmation by others. To achieve this end, they adopt powerful although limited roles that elicit the interpersonal confirmation (praise, rejection, nurturance, etc.) that they crave. When the definition of hysteria is expanded to describe a specific type of interpersonal communication with a specific interpersonal goal, then both sexes can be judged independently of cultural stereotypes.

Halleck (5) assessed the interpersonal impact of the hysteric's behaviors on the receiver and concluded that these behaviors were an effective means of coercing others to respond in a predictable manner.

> The hysteric's demandingness, histrionics and dishonesty should be viewed as purposeful actions designed to structure the interpersonal situation so that she can manipulate the responses of others in a manner which assures their continued interest and affection. (5, p. 750)

When a male is confronted by a female who uses the previously described interpersonal behaviors, his responses will probably include interest, helpfulness,

and guidance. Behaviors that would be inhibited include expressions of aggression, countercomplaints of weakness, and disinterest. The male may also be tempted to respond to the provocative behavior with subtle (or not so subtle) messages about his sexual interest and prowess. Thus we have a situation in which the hysteric's communications about herself have created an emotional climate in the receiver that limits and directs the respondent's behavior to a few choices (9). If neither party actively recognizes what is going on and if the male responds with "continued interest and affection," the interaction will proceed smoothly. If, however, the male attempts to follow up the initial message of provocativeness with sexual behavior, the interaction will often take a turn for the worse, ending with the hysteric outraged at his advances. Halleck (5) views this approach-avoidance behavior as the result of the hysteric's need to control others: "Her sexual charms are suitable weapons in a quest for power since she is less dominated by a need to gratify erotic drives than she is interested in ultimate control of the sexual object" (5, p. 751).

A similar conclusion was reached by Farber (10), who views hysteria as a disorder of the "will," specifically, as excessive willfulness. Willfulness denotes the expansion and distention of the will to the point where the hysteric is completely unyielding to external influences and dominates and subjugates all those in his/her environment. This is accomplished by the forceful use of "personal decoration" in communications with others. The theatrics and histrionics that accompany the communications from hysterics completely overwhelm the content and emphasize the style of the sender. The listener is forced to choose between style and content, and the former easily dominates. The result is that the listener is reduced to making an "aesthetic response," which is usually a response to one of the two implicit questions, "Am I pretty?" and "Am I bright?" Farber also sees conversion symptoms as expressions of willfulness; however, in these cases the body is the object of domination: "What he would not move was paralyzed; what he would not hear deafened him; what he would not see blinded him" (10, p. 106).

BASIC INTERPERSONAL MESSAGE

Imbedded within the hysteric's dramatic overplayed communication is a second-level message or metacommunication. This metacommunication arises from the incongruity of an adult acting like a child or, most commonly, a woman acting like a young girl. The impact of the message is derived from the summation of excessive affectivity, coy provocativeness, gross exaggerations, and play acting. The message basically states, "I am a weak, helpless, frail child and am at your mercy," although, as Farber (10) points out, there can be variations of this implicit message. The covert metacommunication produces the affective response (emotional climate) in the listener, which in turn limits and directs his behavior toward the hysteric. Kell and Mueller (11) observed this aspect of hysterical communication and commented on the incongruity of a message of "weakness" that was very forcefully presented: "Often these clients will utilize a tremendous affective barrage involving highly dramatized speech, tears, and marked affective changes, all of which are intended to intensify the power of the communication that they are fragile" (11, p. 49).

All of the hysterical characteristics I have described are designed to create and fortify the basic interpersonal message, which can be considered the cardinal interpersonal diagnostic sign of hysteria. There is nothing inherent in the communication of frailty and helplessness that excludes males, and a few men do use this interpersonal style (11, p. 53). Luisada and associates (8) reported that the most commonly seen symptom in male hysterics was suicidal thoughts, which tend to elicit attention, concern, and helpfulness when reported to others. Thus it appears that males use different interpersonal behaviors to get the same message across. In fact, only 4 out of the 27 male hysterics in the Luisada and associates study (8) used effeminate interpersonal behaviors.

Paradoxically, the apparently helpless hysteric acts as a powerful agent of interpersonal and environmental control. By simply adopting the helpless role, he/she structures the overall relationship, captures attention, and motivates others to please him/her. Szasz (12, p. 13) originated the concept that the weakness-helplessness role of childhood was the psychological prototype for hysteria; however, his focus was on the implicit communications of conversion symptoms rather than on the overt communicative behavior of hysterics.

Berblinger (6) focused his analysis of hysterical communication on the vagueness and evasiveness of the hysteric's speech. He concluded that the central deficit in hysteria was a lack of introspective ability. The interpersonal approach assumes that the communication and the impact on the receiver is the primary goal of the individual and that internal states (lack of introspective ability) are the result rather than the cause of the adopted role. The same analysis can be applied to the hysteric's vague and global perceptual style (13). When a hysteric is presented with an inkblot stimulus that resembles an animal, her response might be to cover her eyes and look away to demonstrate her fright. Similarly, her verbal report might be "Oh! A wild animal!"—again, emphasizing her fearfulness and weakness. Shapiro (13) argues that this type of perceptual style is a purely internal set; however, it is equally possible that the social and interpersonal consequences of this behavior act to reinforce and maintain the perceptual style. In either case, the affect-laden, vague, and global verbal behaviors convey the specific type of interpersonal message that restricts the future responses from others to those few interactions that confirm the faulty self-perceptions of the hysteric.

INTERPERSONAL GOAL

There is some slight disagreement as to the interpersonal purpose of the hysteric's role, although Farber's questions ("Am I pretty?" "Am I smart?") can be subsumed under Halleck's general observation that hysterics crave continued interest and attention. In both cases, the hysteric appears to want to be interpersonally engaged with others, but on her own terms. MacKinnon and Michels (14) view the hysteric's interpersonal style as a method that allows partial satisfaction of a desire to relate to others but at the same time avoids the possibility of a clear-cut rebuff: "Seductiveness and superficial warmth with the opposite sex permit the avoidance of deeper feelings of closeness, with consequent vulnerability to rejection" (14, p. 120).

The purely interpersonal analysis of the goal of the hysteric's behavior relies on the previously mentioned congruency hypothesis. In this case the hysteric creates an interpersonal world that responds to her in a manner that is congruent with her own self-attitudes. These include feelings of weakness, powerlessness, and worthlessness (except as a sex object). Thus the world responds to her exactly as she predicts it will, and her essential sense of self remains secure.

DEVELOPMENTAL HISTORY

The recurrent interpersonal patterns seen in adult hysterics are the result of long-term social and interpersonal patterns that occurred during the formative years. There is some agreement in the literature that the histories of hysterics are characterized by deprivation of love and attention. What is more significant developmentally are the types of behaviors that were reinforced (albeit infrequently) with love and attention within this generalized state of deprivation.

Much more is known about the developmental histories of female than male hysterics because there are so many more females in this category; therefore, this section will focus on typical histories of female hysterics.

Mothers of female hysterics are often observed to be subtly competitive and envious of their husbands, as well as self-indulgent and unable to spend much time with their children. Often, the only time the mother is willing to pay attention to her daughter is when she is called on to emit behaviors that enhance her and her role, e.g., when her children are sick or hurt and she can demonstrate her "motherliness" to herself and to others. However, she falls short in the less dramatic but more important day-to-day needs of her children, which offer few possibilities for self-enhancement. Thus the child is selectively reinforced for physical disorders; she receives maternal attention only as a result of her frailty, disability, or illness. Hollender (15) feels that this is the crucial moment for the development of the hysteric. The young girl senses that her mother is unable to supply her with the genuine emotional sustenance that she needs: "Young girls, who become hysterical personalities, turn to their fathers not as fathers, but as substitute mothers. Since they barter sexual attractiveness, they grow up to be women who use sex as a means—often the prime means—of obtaining maternal gratifications from men" (15, p. 22).

Not surprisingly, fathers of female hysterics have often been described as superficially charming and mildly seductive. There is often covert strife between husband and wife, which is further exacerbated by the reciprocally seductive relationship between father and daughter. This relationship is often used by the husband as an affront to his wife; thus, the interaction has multiple interpersonal payoffs. In this manner the female child learns that provocativeness is the only sure path to the attention and affection of males and that other females are competitors to be blocked out. Again, as with the mother, the hysteric's father fails to supply her with noncontingent affection and attention. The hysteric soon learns she is constantly in the "manipulative marketplace" (11) in that she must perform a certain role if she is to get gratification. The constant search for gratification is carried out at a high level because of the basic affective deprivation and because whatever gratification she receives is the result of a clear-cut interpersonal trade rather than a spontaneous expression of affection. As a result, the hysteric is never sure that she is loved, since she has performed strenuously to elicit any love she receives. Only when she stops performing and still receives love can she begin to believe in her own inherent worth. Unfortunately, few take this risk since there is always the possibility of an outright rejection.

SELF-ATTITUDES

The net result of this type of childhood is a group of self-attitudes that are interpersonally crippling. The history of playing the coquette for her father and of experiencing the false motherhood role performed by her mother, coupled with the vague impressionistic perceptual style that hides her real feelings and favors externalization, tends to feed back into the hysteric's self-perception. Hysterics often report that they perceive themselves as lacking in substance: "It seems that the hysteric's romantic, fantastical, non-factual and insubstantial experience of the world also extends to his experience of his own self. He does not feel like a very substantial being with a real and factual history" (14, p. 120).

This is the logical result of playing a complementary interpersonal role to others. During childhood the hysteric is called upon to adapt her behavior to the "lead players." Thus she never gets to experience direct power or success. Rather, she is limited to taking on a limited number of roles at the behest of others. This type of recurrent interpersonal experience does not favor the building of a strong sense of personal history or accomplishment.

A second aspect of the hysterics' self-attitudes is the distortion of their perceptions of worth and power. The child soon learns that she is positively regarded for certain attributes (cuteness, seductiveness, weakness) and ignored when she does not display this limited repertoire of behaviors. The only way in which she can contribute to the outcome of a situation is by skillfully integrating her wishes within her performances. This results in a distorted sense of power, in that the desired outcome has to be disguised within a role. Interpersonally, this translates into adult situations in which the hysteric manipulates others with one of her roles (passivity, illness, seductivity, etc.). The manipulator is never given credit for her accomplishments (or failures) since the activity was mediated by another person. This continues the myth that hysterics are weak and others are strong.

Eventually the hysteric believes that she is truly powerless. Her dependency on others is based partially on her subjective feelings of weakness as well as the necessity of involving another person in order to carry out her plans, since she is unable to assume the instrumental role. As time passes, many hysterics build up large reservoirs of hostility directed at those "in power." Developmentally, all expressions of anger were not reinforced and ultimately became incongruent with the developing self-attitudes of passivity, femininity, and girlishness. The only safe way that the hysteric can vent her rage is within her overlearned roles. Interpersonally, this translates into the celebrated "castration" scene. This interaction occurs most successfully when a male accepts a female hysteric's definition of him ("You are strong") and of her ("I am weak"). Within this framework, the male is often tempted to oversell his attributes. As soon as this occurs, the hysteric can allude to a real or imagined weakness, generally in some area of the male's accomplishment, power, or knowledge. The male is often particularly vulnerable, since he has already overstepped the reality of his accomplishments and either ends up defending a lie or admitting his grandiosity. The apparently powerful are temporarily toppled and the hysteric gains some measure of revenge.

The extreme endpoint of indirect control of others is the situation in which the hysteric uses threats of self-destruction to defeat those in her environment. In this interaction a close bond between the players—usually marriage—is a prerequisite, and the husband is often autocratic. The most effective of indirect attacks is self-destruction that is defined as a loss of control or power on the husband's part. The husband is then reduced to the role of guarding his wife and hiding all potential instruments of self-destruction (pills, alcohol, knives, etc.). In this way, the husband becomes the prisoner of his wife's behavior because his exercise of dominance is under her control.

The same sort of approach-avoidance behavior that characterizes the sexual behavior of hysterics also appears in a more general form in their relationships with men. Often the hysteric uses her entire behavioral repertoire in order to attract a new man. Each untried man holds out the possibility of alleviating the original affective deprivation, as well as providing the strength and success that the hysteric feels is out of her direct reach. As soon as the man shows any signs of weakness, the adequacy challenges begin, i.e., the hysteric becomes doubtful that he is "really strong." It often appears that the hysteric is very intolerant of any male sex-role abdication since it destroys the illusion that the male is a savior. Many men married to hysterics learn (perhaps much to their delight) that they must appear hypermasculine in order to allay the anxieties of their wives.

SYMPTOM FORMATION

When an individual with a well-developed hysterical personality structure is stressed by environmental events, two relatively specific classes of symptoms are likely to develop—conversion symptoms and dissociative states. Conversion symptoms can occur in other diagnostic groups (1); however, when they occur in hysterics, they can be viewed as the most potent interpersonal technique in the hysteric's armamentarium. As Szasz (12) has pointed out, this type of interpersonal role forces others to take care of the hysteric, while at the same time absolving her of blame. Perhaps most importantly, it is a situation in which culturally designated hyperadequate males (doctors) will be interpersonally involved. Continued interest and affection are assured as long as the symptoms persist.

The second class of symptoms displayed by hysterics, dissociative reactions, usually occur when the individual has exhausted the interpersonal environment (16). That is, the hysteric finds herself in a situation in which she is unable to elicit the type of responses from others that confirm her basic sense of self. Feedback that is contradictory to the hysteric's self-attitude increases anxiety and sets the stage for flight. In these cases the hysteric abruptly switches roles, an accomplishment limited to those individuals with a long and successful history of role-playing. Perceptually, the hysteric selectively screens out specific classes of stimuli, and when she shifts roles, the classes of perceived and nonperceived stimuli shift as well. The whole process recalls Farber's (10) discussion of willfulness and self-domination, which in these cases relates to an entire social role.

CONCLUSIONS

Hysteria can be viewed as a relatively specific interpersonal style that results from cultural, social, and interpersonal influences. The definition of hysteria has evolved from a symptom-based definition to an interpersonal diagnosis based on specific overt and covert communications that structure the interpersonal environment. The basic communication is one of frailty,

weakness, and helplessness and can be used by both sexes, although cultural factors favor its use by females. The interpersonal role used by female hysterics is an overplaying of the feminine role, which tends to structure the interpersonal environment in a manner that ensures male interest and attention while inhibiting male aggression. More importantly, by restricting the range of responses from others, the hysteric ensures that those responses which have been elicited will be confirmatory to and congruent with her own self-attitudes. The lack of affective conciseness, coupled with the often superficial and flirtatious relationships with men, suggests that these behaviors help the hysteric avoid commitments and substantive relationships with males that present the possibility of direct rejection. The vague and global perceptions of the hysteric, often thought to be at the core of the hysteric's personality, may be the consequence of external reinforcement, since the style of perception aids in structuring the environment.

The developmental histories of female hysterics suggest that they are selectively reinforced for certain interpersonal roles, including illnesses, frailty, seductiveness, and passivity. These roles probably feed back into the self-attitudes of hysterics, particularly in regard to their feelings of worth and power. Goal-directed behavior is often indirect and limited to influencing the behaviors of others.

Finally, the typical symptoms in hysterics reflect the roles of weakness, passivity, and frailty. Often the symptoms involve the interpersonal engagement of physicians, which is assumed to be highly reinforcing for this group.

1976 Anniversaries

BY GEORGE MORA, M.D.

The author recalls this year's anniversaries of events and individuals prominent in the history of medicine, psychiatry, and psychology and examines their practical or theoretical contributions.

1676

Sir Matthew Hale, a British Lord Chief Justice who was born in 1606, died in 1676. Hale maintained an active interest in the legal aspects of insanity throughout his long judiciary career. His *History of the Pleas of the Crown* (1736) was said to have influenced eighteenth- and nineteenth-century lawyers more than any other single work on the subject of law and insanity. Under "ideocy," i.e., idiocy and imbecility, he considered *fatuitas a nativitate* (stupidity from birth) and *dementia naturalis* (inborn witlessness).

According to Hale, some degree of stupidity had to be present in a defendant for a successful defense of insanity. The tests of intelligence he used were based on the person's ability to reach the level of discretion, that is, the age of 14. Although not conclusive, this evidence had to be brought forward to the jury (Hale was also a strong supporter of the jury system). *Dementia accidentalis* (acquired insanity) was distinguished from witlessness from birth in his view, and permanent insanity was distinguished from insanity interpolated with lucid intervals. The distinction that Hale made between total insanity and partial insanity (disorder of only certain functions with unimpaired reason) remained a basic legal tenet for three centuries. Hale also held that cases of *dementia affectata* (insanity due to influence of toxic substances) constituted a special category.

From the practical viewpoint, Hale emphasized that the focus in legally determining insanity not be on the action performed by the defendant but on his or her state of mind. Therefore, in cases of homicide it was important to pass a judgment on the state of mind of the defendant because a verdict of acquittal could be obtained in cases of insanity.

The new Bethlem, that is, a newly rebuilt Bethlem Hospital, was opened in London. This hospital, originally built in the thirteenth century and then placed under the protection of the City of London in the following century, was seized by the Crown in 1375; at that time it had already been used for acutely ill mental patients. Returned eventually to the city in 1546, Bethlem had become increasingly dilapidated by the time of the great fire of London in 1666. It was then decided to build a new Bethlem Hospital on land made available at Moorfields, where Liverpool Street Station now stands. The new construction, built by the architect Robert Hooke in a grandiose style at a cost of £17,000, was considered more like a palace than a hospital. It was intended to be a reproduction of Tuileries Palace in Paris, a fact that apparently considerably offended Louis XIV. Prints of the building show an imposing frontage surrounded by pleasant greenery. Over the stone piers of the great gate sprawled two colossal statues—after the fashion of Michelangelo's "Night and Morning" in Florence—intended to represent two phases of mental disorders, dementia and acute mania. Beyond the door were the "Penny Gates," where the visitor put a penny in the money boxes. To the right and left of the entrance hall on both stories of the building were the galleries of the patients.

1776

David Hume, who was born in Edinburgh in 1711, died in 1776. Hume was influenced by natural philosophy in Scotland. In 1734 he moved to France, where he wrote *A Treatise of Human Nature* (1739), which attempted to introduce the use of the experimental method into the study of man. However, this important work passed largely unnoticed, while more attention was given to *An Enquiry Concerning Human Understanding and the Principles of Morals* (1751).

Hume's importance in the history of psychology lies in his contribution to sensistic associationism. Influenced by Locke, Berkeley, LaMettrie, Hartley, Rousseau, and others, Hume's thinking represents the final expression of the empirical school. Basing his criticism of knowledge in a careful recording of experiential data, Hume differentiated immediate impressions from ideas in the process of perception: impressions consist of sensations, passions, and emotions "which enter with most force" into consciousness; ideas are "faint images of these," "copies of our impressions." Moreover, although impressions are limited, thought is not tied either to nature or to reality; thought is the creative force of the spirit. Hume described three

Dr. Mora is Medical Director, Astor Home for Children, Rhinebeck, N.Y., and Research Associate, Department of History of Science and Medicine, Yale University, New Haven, Conn. Address reprint requests to him at 32 Slate Hill Drive, Poughkeepsie, N.Y. 12603.

modes of association in the connection of successive ideas: resemblance, contiguity, and causality; these were eventually reducible to resemblance and contiguity in experience. In essence, Hume's psychology employs a strict empirical method and advances the epistemological conclusions that all knowledge is knowledge of experiences and that the relations of things in themselves can never be known. Indeed, the ego is nothing but "a bundle or collection of different perceptions," and the identity of the person is the result of the operation of imagination.

Hume's concepts greatly influenced Kant's critical philosophy in Germany and both the associationistic and the psychological trends in philosophy in England. At the beginning of the twentieth century, Hume was viewed as one of the main initiators of psychological elementarism; more recently, he has been considered a forerunner of phenomenological ideas.

Johann Kaspar Spurzheim was born at Longvick, Germany, near the city of Treves on the Moselle River. While in Vienna studying medicine, Spurzheim came under the influence of Franz Joseph Gall, who believed in the study of the human brain, and especially of the cortex, as the material basis of all mental and moral activity, the instrument through which all psychic manifestations take place.

Gall and Spurzheim emphasized the characteristics of the various areas of the brain ("organology") that developed in different ways because of different myelination. Because the skull is molded on the brain, they believed, it is possible to determine the shape of the brain by examining the shape of the skull.

Gall and Spurzheim were fine anatomists. Their system of psychophysiology centered around four main points: 1) moral and intellectual qualities are innate (this point was at variance with the tenets of sensism); 2) the functioning of these qualities is strictly related to the organic structure (for this belief Gall and Spurzheim were accused of materialism and of fatalism); 3) all of the faculties and feelings are localized exclusively in the brain (this idea conflicted with the idea that passions are localized in the thorax or in the abdomen); 4) rather than "the organ of the soul," the brain is composed of as many organs as there are faculties, tendencies, and feelings. Specifically, Gall described 25 centers, of which man had 19 in common with animals and 8 specific to man, including the organ of religion. This last idea did not prevent Gall's lectures from being prohibited in 1802 as antireligious.

After an extensive teaching tour through several German cities, Gall and Spurzheim eventually settled in Paris in 1807 and established a successful medical practice. Between 1810 and 1819 their four-volume work *Anatomie et Physiologie du Système Nerveux en Général et du Cerveau en Particulier* appeared. The first two volumes were coauthored by Spurzheim and Gall, and the last two were written by Gall alone. Spurzheim left Gall in Paris in 1813 and spent time in France, England, Scotland, and Ireland. He finally accepted invitations to come to the United States.

Phrenology had already been recognized in the United States due to the crusading attitude of Dr. Charles Caldwell from the medical school of Transylvania, a number of books on phrenology, and the *Phrenology Journal and Miscellany*, first published in Edinburgh in 1823. Perhaps one reason for the success of this movement in the United States was the liberal and progressive stance embraced by phrenologists in the fields of education and penology. After his arrival in New York City on August 4, 1832, Spurzheim stopped on his way to Boston at Yale and then at Hartford, where he met with Dr. Amariah Brigham, who founded the *American Journal of Insanity* in 1844. Spurzheim gave two very successful series of lectures in Boston but became ill suddenly and died in Boston on November 10, 1832. On the day of his funeral, November 17, the Boston Phrenological Society was founded; it remained active until 1842. Spurzheim's skull, heart, and brain have been preserved among the specimens in the collection of this society.

Phrenology later became known in the United States through the work of George and Andrew Combe, Samuel Gridley Howe, Horace Mann, and L.N. and O.S. Fowler. By the 1840s, when enthusiasm for phrenology began to decline, it had been embraced by several outstanding psychiatrists, such as Pliny Earle, John Galt, Isaac Ray, Samuel Bayard Woodward, and Amariah Brigham.

Johann Friedrich Herbart was born in Oldenburg, Germany. Educated at the University of Jena under Fichte, Herbart obtained his doctorate at Göttingen in 1802. From 1809 to 1833 he was professor of philosophy in Königsberg, where he succeeded Kant; from 1833 to his death in 1841 Herbart was professor of philosophy at Göttingen. In opposition to the concept of faculty psychology, Herbart conceived of mental images as conflicting among themselves and as emerging to the threshold of consciousness (a term he coined) according to their strength and the impact of inhibitions. He attempted to express these mechanistic concepts in mathematical terms.

In direct contrast to the vague ideas of the contemporary *Naturphilosophie* and of idealistic philosophy, Herbart's concrete representation of the psychic mechanisms had great appeal for their realism; in retrospect, however, it appears to have overlooked the unity of the personality. Regardless of this, Herbart's theories had considerable following in education, especially in emphasizing the positive value of proper experiences in very early life. In psychology, his concepts were the basis of psychometrics, of Wundt's emphasis on apperception, and of the ideas of the unconscious in the late nineteenth century. Among Herbart's works are *Compendium of Psychology* (1816), *Psychology As Science* (1824, 1825), *Encyclopedia of Philosophy* (1835), and *Psychological Research* (1839).

1876

William Maclay Awl, who was born in Harrisburg, Pa., in 1799, died in 1876. Awl studied medicine at the University of Pennsylvania in 1819 and 1820. He settled as a practitioner in Columbus, Ohio, in 1833. Recognizing the need for a facility for the mentally ill in Ohio, he was instrumental in founding the Ohio State Asylum for the Insane, which was opened in 1838; he was elected superintendent of that institution. Awl was among the 13 founders of the Association of Medical Superintendents of American Institutions for the Insane (now APA). He was elected Vice-President of the Association in 1846 and President in 1848.

Awl's name is especially remembered in connection with the so-called cult of curability (i.e., the belief that mental illness could be cured) of the early nineteenth century. In an 1843 report of the Ohio State Lunatic Asylum, Dr. Awl stated, "Per cent of recoveries on all recent cases discharged the present year, 100." Because of this, he came to be known among his contemporaries as Dr. Cure-Awl.

Samuel Gridley Howe, who was born in Boston in 1801, died in 1876. Howe was acclaimed as a hero for his participation as a soldier and a surgeon in the Greek war for independence from Turkey (1824–1830). By the time he was named head of the New England (Perkins) Institution for the Education of the Blind in 1832 (a position he maintained until his death), he had already achieved international fame as the teacher of Laura Bridgman, the first blind deaf-mute successfully educated by systematic means. Howe placed this pupil in contact with the world.

Under the influence of Spurzheim, who had come to the United States on a lecture tour, Howe became an ardent phrenologist. He was elected corresponding secretary of the newly established Boston Phrenological Society and was involved in maintaining a museum of phrenology that contained the skulls of many people, including Spurzheim. In 1838, a strong relationship developed between Howe and George Combe, an attorney converted to phrenology by Spurzheim two decades earlier who had come to Boston on a speaking tour.

Howe claimed that a proper body-mind relationship, a sound educational system, high morality, and even Christian ideals could be obtained through phrenology. He reached the highest degree of faulty phrenological reasoning in an article titled "The Heads of Our Great Men" (1838), in which he attempted to justify the soundness of the phrenological doctrine through post hoc reasoning. By the 1840s the phrenological movement, which had been embraced by some distinguished psychiatrists, began to fade, and the "science" of phrenology fell into the hands of all sorts of quacks.

In Milan Cesare Lombroso's work on the delinquent man, *L'Uomo Delinquente Studiato in Rapporto alla Antropologia, alla Medicina Legale ed alle Discipline Carcerarie*, appeared. The book was translated into the main languages soon after its publication in Italian. Cesare Lombroso was born into a Jewish family (probably from Spain) in Verona, Italy, in 1835. Through the indirect influence of Giambattista Vico (1668–1744), the Italian philosopher of history, Lombroso became interested in the socioanthropological study of cultures. While studying medicine at the universities of Pavia, then Padua, and then Vienna, Lombroso was attracted to the studies on magnetism, hypnosis, somnambulism, and dreams of G.H. von Schubert, J. Kerner, and L.F.A. Maury. Lombroso began to elaborate on the relation between dreams and insanity and on the regressive metamorphosis (similarities between individual and cultural or ethnic primitive expressions of behavior). In this study he found evidence for the influence of civilization on insanity. After graduation from the medical school of Pavia in 1858, Lombroso embarked on the long-term study of cretinism, which was then endemic in certain areas of Italy. At the same time he maintained a long-standing interest in the prevention of diseases and the fight against illiteracy.

In 1864 Lombroso presented his first study on genius and insanity at the University of Pavia. This later developed into *The Man of Genius* (English translation, 1891), which was based on a supposed correspondence between organic dispositions and moral tendencies. Against the traditional spiritualism in legal medicine, Lombroso advocated a bioanthropological study of the individual delinquent. He found justification for this view in the supposed "atavic" characteristics of many delinquents and their similarities with "inferior" races. Aside from some interest in the study of pellagra during 1863–1870, Lombroso continued to dedicate himself to the study of delinquency; he was the founder of the field of criminal anthropology.

In *The Delinquent Man* Lombroso emphasized the degenerative aspects of the delinquents he studied and advocated the substitution of social responsibility for moral responsibility and of prevention and therapy for punishment. Named professor of legal medicine in Turin in 1876 and professor of psychiatry there in 1880, Lombroso, with some colleagues and pupils, launched the magazine *Archivio di Psichiatria, Antropologia Criminale e Scienze Penali*, which was devoted to the concrete study of the mentally ill and of the delinquent. The magazine soon gained ample recognition and was imitated in other countries.

Eventually, Lombroso came to consider many "morally insane" individuals to be affected by latent forms of epilepsy. He advocated the substitution of hospitals for jails for the criminally insane and stated that more of the geniuses of the past than were thought so had been insane. These radical views, coupled with Lombroso's disregard for the rising fields of histopathology and neurophysiology, contributed to the fact that many students opposed his theories.

In time, Lombroso and his pupils became involved in the study of such other fields as political crimes, so-

cial and collective psychopathology, anarchism, psychopathology in women, and, finally, psychic science. Increasingly dissatisfied with the political and religious climate of Italy, Lombroso became a militant in the newly organized Socialist party there and did his best to improve the conditions of workers. He died in 1909.

In London *The Functions of the Brain* by David Ferrier appeared. Ferrier was born in Scotland in 1843. He was educated at the University of Aberdeen, where he came under the influence of Alexander Bain, and the University of Edinburgh. Following his graduation in medicine in 1870 Ferrier moved to London, where he lived until his death in 1928. In 1873, while experimenting on the animal brain at the West Riding Lunatic Asylum, Ferrier caused convulsive twitching or gross movements of particular muscles of the head with minimal currents from electrodes inserted in particular areas of the brain in a variety of animals. Although he was able to establish the motor area and certain sensory areas and eventually to map the entire motor cortex, he was not misled by the concept of cerebral localization. For Ferrier, the functions of the cerebrum were sensorimotor; this idea anticipated the modern concept of the brain as the organ of interaction.

In 1878, with John Hughlings Jackson, Sir John Bucknill, and Sir James Crichton-Browne, Ferrier founded the journal *Brain*. Connected chiefly with the National Hospital from 1880, Ferrier occupied the chair of neuropathology created for him at the Medical School of King's College in 1889. He was bestowed with many honors, including being named laureate of the Institut de France in 1878 and knighthood in 1911. In retrospect, he can be considered the link between Hughlings Jackson and Sherrington because he worked with Jackson in the 1870s and Sherrington worked with him in the 1890s.

William James inaugurated a course in experimental psychology, the first in the United States, at Harvard University. James was born in New York City in 1842 to an illustrious family. He was graduated from Harvard Medical School in 1869. While traveling in Germany in 1867–1868 he was impressed with the advances made there in the study of sensorial physiology and psychology. Although he was concerned with the need to establish psychology on an exact basis as a natural science, James admitted that its object is something entirely different from physical realities. James seemed unable to reconcile this apparent dichotomy, which is reflected in his own academic orientation: he taught philosophy at Harvard until 1889, then psychology for almost a decade, and philosophy again from 1897 on.

Generally recognized as the first great representative of American psychology, James strongly believed in a psychology of direct experience. *The Principles of Psychology* (1890), followed by *Psychology: Briefer Course* (1892), which were translated into several languages, gave James renown all over the world. Central to his view was the idea of a stream of consciousness or of thought that affects even the simplest psychic occurrence between stimulus and reaction. Sensation and thought are therefore seen to be in continuous states of fluctuation.

James distinguished between substantial and transitive ways of experiencing reality: the former related to particular content; the latter connected one experience to another. Also important in his theory was the differentiation between topic and focus of consciousness and fringe of consciousness. The stream of consciousness—the psychic reality—cannot be separated from corporeity; the emotions themselves are the result of bodily processes through the action of the neurovegetative system. This idea, which was supported by Carl Georg Lange (1834–1900) of Denmark, came to be known as the James-Lange theory of emotions. This theory was subjected to a great deal of criticism.

In James' view movements become simplified and selected and conscious attention decreases through the formation of habits. The identity of the individual experience, of the ego, or of the person is a temporal and structural element in the context of the stream of consciousness, to be viewed by the individual as ego in retrospect and as initial action in prospect. Language, which James felt was not appropriate for psychological phenomena, alters the original psychological experience by hypothesizing elements of reality and may be erroneously conceived of as the psychological reality itself. This idea caused a fundamental semantic problem because the only experienced reality is the one that can be verbalized.

In essence, according to James mental life must be studied as a whole and consciousness as a continuous stream. Unconcerned with any specific methodology, in contrast to Wundt, James neglected laboratory work. He turned over his laboratory to Hugo Münsterberg as soon as Münsterberg decided to remain at Harvard. In line with the American temperament, James preferred to study the mind from a functional perspective, which included unconscious, physical, abnormal, and animal behavior as well as religious experience, on which James wrote the pioneering *The Varieties of Religious Experience* (1902). Later in his career, James became one of the exponents of the philosophical movement of pragmatism, which he presented in his successful volumes *Pragmatism* (1907), *A Pluralistic Universe* (1909), and *The Meaning of Truth* (1909). He died in 1910.

James was a forceful personality and a convincing teacher and writer; his greatest accomplishment consists in his establishing psychology in the academic tradition. In the two decades after his death some of his main concepts were presented in different forms by Dilthey, by Husserl, and by the representatives of the Gestalt school. In recent years James has been considered by some a forerunner of the existentialist movement.

Constantin von Economo was born to noble and

wealthy parents in Braila, Romania. Von Economo grew up in an environment in which Greek, Italian, French, and German were all spoken. After his graduation from the medical school in Vienna in 1901, he practiced in Paris, Nancy, Strasbourg, and, later, in Munich under Kraepelin and Alzheimer. Back in Vienna in 1906, Von Economo became privatdozent in neurology and psychiatry and, later, professor in the psychiatric clinic, which was then under the direction of Wagner von Jauregg.

Von Economo's early studies dealt with the physiology and anatomy of the midbrain. His name is mainly remembered, however, for the discovery of the encephalitis lethargica that assumed epidemic proportions in 1917. Von Economo described this disease's clinical symptoms (e.g., disturbances of sleep, chorealike movements, and neuralgias) and the anatomopathological findings in the brain. He wrote a thorough monograph on the subject in 1929. In the field of pure brain research, Von Economo developed the concept of progressive cerebration, i.e., progressive evolutionary complexity of the cerebral functioning from early times on. In 1925 Von Economo published a text and an atlas of the citoarchitecture of the adult human cerebral cortex. He died in 1931.

Elmer Ernest Southard was born in South Boston, Mass. Southard excelled in his studies at the Boston Public Latin School and as a masterful chess player; he won many championships. While at Harvard University he was influenced by Josiah Royce in the field of philosophy and by William James in the field of psychology. While enrolled at Harvard Medical School in 1897, Southard was attracted to the study of pathology. After his graduation in 1901 he spent several months traveling in Europe; he returned to England in 1907 to work in Sherrington's laboratory in Liverpool.

Named instructor in neuropathology in 1904 and assistant professor in 1906 at Harvard, Southard also accepted the position of assistant physician and pathologist at the Danvers State Hospital, Mass., in 1904. Already well known for his many publications, he was named Bullard Professor of Neuropathology at Harvard Medical School in 1909; at the age of 33, Southard was probably the youngest man to be promoted to such a senior position (the department of neuropathology became a separate unit of the school at this time). At the same time, he was named to the newly created position of pathologist to the State Board of Insanity of Massachusetts.

One of Southard's principal achievements was the opening in 1912 of the Psychopathic Department of Boston State Hospital, which was conceived of as a center for prevention, observation, diagnosis, and short-term treatment of mental illness; patients were often accepted on an emergency basis here. More than 1,500 patients were treated here in the department's first full year of operation, 1913; nearly 2,000 were treated in 1914. In a short time the Psychopathic Hospital, under Southard's leadership, became well known as an educational center not only for students in medicine and psychology but also for students in ancillary disciplines. It is there that such distinguished American psychiatrists as Lawson Lowrey, Karl Menninger, Harry C. Solomon, and Karl Bowman received their training.

As early as 1911, Southard was clearly aware of the importance of social work. He appointed Mary C. Jarrett chief of social services at Boston Psychopathic Hospital. This department grew into the Training School of Psychiatric Social Work affiliated with Smith College in Northampton, Mass., in 1918. Considerable support for this project came from the National Committee for Mental Hygiene, founded by Clifford Beers in 1909, in which Southard was deeply involved. Out of Southard's interest in industrial psychiatry, for which he anticipated a considerable development, came his recommendation for a triadic working party among psychiatrists, psychologists, and social workers to be employed in juvenile courts and schools. This idea found its most fertile ground in the field of child psychiatry. Southard and Jarrett's volume *The Kingdom of Evils*, which appeared in 1922 (2 years after Southard's death), represented a comprehensive effort to overcome the most common social impediments to mental health, in particular, diseases and deficiencies, educational errors, vices and bad habits, legal entanglements, and poverty.

Southard openmindedly encouraged trials of psychoanalytic examinations at the Psychopathic Hospital. His personal attitude, however, was rather critical of the Freudian theory of pansexualism, the "emotional monism" inherent in it (at variance with the pluralism of the American philosophical tradition), and what he felt was dogmatism on the part of the Freudians. He castigated this dogmatism in his famous paper "The Mind Twist Versus Brain Spot" (1914). At the base of Southard's aversion toward psychoanalysis was probably his own exuberant personality, which he himself considered hypomanic and which accounted for his tremendous energy, as it contrasted to Freud's pessimistic orientation. In 1919 Southard published a paper titled "Sigmund Freud: Pessimist."

Shying away from the emphasis on classification of mental disorders, Southard supported instead the application of pragmatic psychiatry, for which he elaborated a "Key to the Practical Grouping of Mental Diseases" based on 11 groups. Among his most original contributions to psychopathology was a fundamental article on "The Application of Grammatical Categories to the Analysis of Delusion," in which he developed the evolutionary idea of a layered development of moods from the imperative among the savages through the indicative up to the subjunctive and optative in higher civilizations. Southard's major research centered around the study of the neurological aspects of syphilis, on which he and Harry C. Solomon published the ample monograph *Neurosyphilis* in 1917. That same year Southard was asked to assume the direction of the Boston unit of the U.S. Army Neuropsy-

chiatric Training Center. In 13 months he prepared 20 articles and 1 book, *Shell Shock* (1919), on the subject of shell shock.

Ideas for research continuously sprang from Southard's fertile mind, resulting in constant inspiration for all those who came in contact with him, including physicians, psychologists, artists, and literary men and women. The last year of his life, 1919, was marked by satisfaction as well as by disappointments. Elected President of the American Medico-Psychological Association (now APA), he was already experiencing difficulties in his work that resulted in his resignation as director of the Psychopathic Hospital and his appointment as director of the Massachusetts State Psychiatric Institute. The following year, 1920, he died suddenly of an acute infection.

In retrospect, Southard's main achievements were those of an educator. Because of his untimely death, it has been properly said, "He flashed across the psychiatric sky like a comet." Perhaps his very versatility prevented him from accomplishments in psychiatry as great as the magnitude of his genius. Probably aware of this situation, Southard once said laughingly but, perhaps, also sadly of himself, "Among psychologists I am known as a chess player . . .; among psychiatrists I am known as an anatomist; among philosophers I am known as a psychologist; and among clinicians as a neuropathologist."

Thomas W. Salmon was born in Lansingburgh, near Troy, N.Y. By the time he was graduated from Albany Medical College in 1899, he was attracted to two different subjects, bacteriology and psychiatry. Appointed bacteriologist to the Willard State Hospital in Ovid, N.Y., he was influenced by Dr. William L. Russell, then one of the leaders in psychiatry. In 1907, 4 years after joining the United States Public Health Service, Salmon was put in charge of the psychiatric evaluation of immigrants arriving at Ellis Island, N.Y. There he attempted to introduce a valid psychiatric examination for large numbers of people (more than 1 million in 1907 alone). In 1911, after a 4-year period at the Marine Hospital in Chelsea, Mass., Salmon was granted a leave of absence to serve as chief medical examiner of the Board of Alienists for the New York State Commission on Lunacy. In this job he made the first graphic statistical charts for state hospital populations and worked very hard toward improving the immigration laws.

By 1911 the movement for mental hygiene was rapidly spreading in the United States, following the publication of *A Mind That Found Itself* by Clifford Beers in 1908 and the establishment of the National Committee for Mental Hygiene. With the help of a grant from Mr. Henry Phipps and, later, from the Rockefeller Foundation, Dr. Salmon was named first medical director of the National Committee for Mental Hygiene in 1912. By 1914 he was engaged in an attack on the problems of mental deficiency with the help of the State Charities Aid Association. In 1917, at Dr. Salmon's suggestion, the magazine *Mental Hygiene* was started under the editorship of Dr. Frankwood E. Williams, who was the assistant medical director of the committee.

By the outbreak of the war in 1917, the National Committee for Mental Hygiene had devised a plan for establishing a central psychiatric unit for the military expedition, for excluding all unstable individuals from military service, and, in general, for involving psychiatrists in the military campaign. On his arrival in France at the end of 1917, Maj. Salmon plunged into his work as director of psychiatry for the American Expeditionary Force. He worked toward the training of competent psychiatric professionals and the organization of a camp hospital exclusively for the treatment of neuroses. Rejecting the loose term "shell shock," Salmon established guidelines for the early detection of neuroses and psychoses and began to plan for the return to the United States of the many psychiatric casualties. At the end of the war, Salmon helped write volume 10 of the *Report of the Medical Services in the World War*.

After his return to the United States at the end of the war, Salmon worked hard to develop plans for hospitalizing mentally disabled veterans as special consultant in neuropsychiatry to the Surgeon General. This work resulted in the organization of the Veterans' Bureau in 1921. In 1922 Salmon resigned from the National Committee for Mental Hygiene and accepted a professorship of psychiatry at Columbia University. There he became involved in establishing a program of preventive psychiatry, mainly through the opening of child guidance clinics in various cities with the help of the Commonwealth Fund, and, later, by organizing the New York State Psychiatric Institute, which opened in 1929 on the grounds of the Columbia Medical Center. Among the honors Salmon achieved was the Presidency of APA in 1923–1924, the U.S. Army's Distinguished Service Medal, and promotion to Brigadier General in the Medical Officers Reserve Corps. Salmon died in 1927 at the age of 51 in a sailing accident. Since then a Thomas William Salmon Memorial Lecture has been given annually in New York City under the sponsorship of the National Academy of Medicine.

Clifford Beers was born to a distinguished family in New Haven, Conn. After his graduation from Yale in 1897 he entered a business career, but 3 years later he succumbed to mental illness. Spared from a suicide attempt, Beers spent the next 3 years in different mental institutions: a private profit-making asylum, a private non-profit-making asylum, and, finally, a state hospital. In all three institutions he experienced harsh treatment from ignorant attendants and disinterest on the part of professional staff. Clinically, he suffered from delusions of persecution and self-reference, followed by a period of profound depression, which, in turn, gave way to a state of extreme exaltation. While in this last state he developed the idea of starting a worldwide movement for the protection of the insane.

Emerging as a newly cured man in 1903, Beers decid-

ed that a book not unlike *Uncle Tom's Cabin* that recounted his personal experience might best help the cause of the mentally ill. He therefore wrote the highly successful *A Mind That Found Itself*, which was composed in a frantic way between 1905 and 1907 and has been reprinted uninterruptedly since 1908. Beers received the enthusiastic support of William James and Adolf Meyer in this endeavor. Essentially, the book makes a plea for establishing a national society interested in improving the care and treatment of the mentally ill, for disseminating information concerning mental illness to all groups of people, and for encouraging research into the causes and outcome of mental illness.

Under the advice of William James and Adolf Meyer, who suggested the term "mental hygiene," Beers launched the Connecticut Society for Mental Hygiene in 1908 and the National Committee for Mental Hygiene in 1909. He was appointed permanent secretary of the national committee. In spite of two considerable difficulties from the beginning, i.e., the financial strain (which was eventually overcome with the help of John D. Rockefeller, Henry Phipps, and others) and the contrast between Beers's propagandistic emphasis and Meyer's scientific approach, the chief objects of the society eventually crystallized into working for the protection of the mental health of the public, raising standards for the care of the mentally ill, promoting the study of mental disorders, disseminating this information, obtaining reliable data in regard to mental disorders, and coordinating efforts with the federal government and with state organizations.

With unrelenting energy, Clifford Beers guided the mental hygiene movement toward new fields, mainly the establishment of the Training School for Psychiatric Social Work in 1918 at Smith College, the development of the child guidance movement with the help of the Commonwealth Fund in 1922, the sponsoring of a psychiatric study of prisoners at Sing Sing Prison by Bernard Glueck in 1917, and the application of mental hygiene to problems of industry. In 1918 there were 17 state societies for mental hygiene in the United States; by 1935, there were more than 50 state and local societies. In 1930, at the first international congress on mental hygiene, held in Washington, D.C., and attended by more than 3,000 persons representing 50 countries, the International Committee on Mental Hygiene was founded. A second international congress on mental hygiene was held in Paris in 1937, and a third met in London in 1948. It was there that the World Federation for Mental Health was founded.

Beers died at Butler Hospital, Providence, R.I., in 1943.

Charles MacFie Campbell was born in Scotland. After graduating from the Medical School of Edinburgh Campbell practiced in Paris under Pierre Marie, in Heidelberg under Nissl, and in the United States under Adolf Meyer at the New York State Pathological Institute at Ward's Island, N.Y. Campbell eventually joined Dr. Meyer permanently, following him to Baltimore, where Campbell became associate director of the Henry Phipps Psychiatric Clinic and associate professor of psychiatry at the Johns Hopkins Medical School (1913–1920).

An excellent teacher, Campbell was named director of the departments of psychiatry of Harvard Medical School and the Boston Psychopathic Hospital after the death of E.E. Southard. In 1925 Campbell edited *Problems of Personality: Studies Presented to Dr. Morton Prince, Pioneer in American Psychopathology*. In 1934, he delivered the Salmon Lecture, "Destiny and Disease in Mental Disorders," which was published as a book the following year. In this book (1) Campbell emphasized emotional factors in the development of schizophrenia:

> The problem of the psychiatrist was . . . to get to grips with the actual dynamic situation, to reconstruct in detail the life history, with the attention to the sensitizing or conditioning influence of environmental factors, and with due appreciation of the nature of emotional disturbance, of substitutive and evasive reactions, of symbolic expressions, of the various modes of getting satisfaction for the complicated needs of the individual. (pp. 33, 34)

Elected President of APA in 1937, Campbell made a plea for the involvement of psychiatry in the prevention of war and the control of aggression at the international level in his Presidential Address on "Perspectives in Psychiatry." He died in 1943.

Presence and Persistence of Depressive Symptoms in Patient and Community Populations

BY THOMAS J. CRAIG, M.D., M.P.H., AND PEARL A. VAN NATTA, M.A.

The authors used a questionnaire to assess presence and persistence of 16 depression-associated symptoms in two inpatient groups and a random community sample. Nondepressed inpatients were more likely than the community population to experience psychological symptoms of depression, but persistence of the symptoms was the same for both groups. In contrast, significantly more depressed patients than community respondents indicated presence for all but 2 symptoms and persistence for all but 1. Thus persistence of symptoms may be more specific to depression than mere presence.

INTEREST in the prevalence of psychiatric symptoms and mental illness in general populations has produced studies that document a relatively high frequency of symptoms in diverse settings. These reports suggest that, at any given time, a large proportion of the community is suffering from a psychiatric disorder (1–3). Most of these investigations used reports of presence or intensity of symptoms (4–6) as their measure of pathology, although duration of symptoms has recently been suggested as a more crucial factor in determining whether true illness exists (7). In addition, most of the studies used an overall score composed of an aggregation of symptoms, and many reports focused primarily on symptoms representative of general psychopathology rather than on a discrete syndrome such as depression. Thus, the power of the discrimination of the score is limited to a generalization like "neurotics" have more symptoms than "normals" (6).

This study estimates the presence and persistence of 16 symptoms considered to be characteristic of the depressive syndrome in a community sample and compares the results with those for inpatients of a psychiatric facility that serves the community. The specific question we investigated was, Which symptoms best discriminate by either their presence or their persistence among depressed inpatients, nondepressed inpatients, and community respondents?

METHOD

As part of the Community Mental Health Epidemiology Program, initiated by the Center for Epidemiologic Studies (CES) of the National Institute of Mental Health (NIMH) in 1971, an interview survey of the general population was carried out in Washington County, Md., in 1971–1973. Households were selected at random from the Washington County master list, and one respondent, age 18 or over, was randomly selected from each household for interview. The response rate was 80.5% (N=1,672). Details of the survey have been published elsewhere (8).

The questionnaire contained 435 items, grouped under 13 sections, and took approximately 45 minutes to complete—major emphasis was on depressed mood and related symptoms. One of the scales used was the

Dr. Craig is Assistant Professor, Department of Psychiatry and Behavioral Science, the Johns Hopkins University School of Medicine, and Ms. Van Natta is Research Associate, Department of Epidemiology, the Johns Hopkins University School of Hygiene and Public Health, Baltimore, Md. Address reprint requests to Dr. Craig, 40 Woodbine Rd., New York, N.Y. 10956.

This study was supported in part by Alcohol, Drug Abuse, and Mental Health Administration contract HSM-42-71-32 from the National Institute of Mental Health.

The papers in this section are grouped around a specific topic. Publication here does not, however, imply that the Editor considers this material to constitute a comprehensive analysis of the topic.

CES-D, a self-administered depression scale of 20 items, most of which were taken from 1) the Zung Scale (9), 2) the Beck Scale (10), 3) the D scale of the Minnesota Multiphasic Personality Inventory, 4) Raskin's self-report rating of depression (11), and 5) a scale developed by Gardner for use in population surveys (12). The score developed for the CES-D has a potential range of 0–60 and is the summation of the scaled responses. The weightings were as follows: 0, if the person reported no days with the symptom; 1, if the symptom lasted 1–2 days; 2, if 3–4 days; and 3, if 5–7 days. For the purposes of this paper, each symptom is considered separately as it was reported in terms of its presence (weights 1–3) and persistence (weight 3) over the week preceding the interview.

In addition to the community survey, the same questionnaire was given to 65 inpatients, aged 18–75 years, at a private psychiatric hospital serving Washington County. One of the interviewers from the community survey administered all the hospital interviews. A previous report found no significant difference between the mean CES-D scores of respondents from the general population interviewed by this interviewer and those of the respondents interviewed by the other community interviewers (8). The head nurse selected subjects on the basis of their ability to cooperate with the study, and the nurse-clinician assigned to the patient's therapy team rated him/her for depression on a scale described by Rockliff (13). The patients were interviewed immediately thereafter.

We use "presence" of a symptom to refer to a respondent's report of having experienced the symptom for 1–7 days during the week preceding the interview. "Persistence" of a symptom refers to the respondent's report of having experienced the symptom for 5–7 days during the week preceding the interview. The judgment of whether a patient was depressed or nondepressed was based on the nurse-clinician's rating of each patient's behavior on the Rockliff depression rating scale (13). The score for the Rockliff scale has a range of 0–30 and is a summation of ratings on each of 10 items. A person is given a rating of 0–3 on each item, indicating degrees of depressive symptoms from none to severe.

Each of the 30 depressed patients had a rating of 6 or more. The 15 nondepressed patients were rated 0–3; none earned a rating higher than 1 on any individual item. This is a more stringent definition of depression than that suggested by Rockliff and excludes patients whose ratings were 4 or 5. Also excluded were 12 schizophrenic patients who showed no reliable correlation of interview scores with nurses' ratings (14). The criterion of depression is thus based on symptoms, not on diagnosis, and may be considered more analogous to the depressive syndrome than to depression as a disease (15).

Since presence of a depressive symptom could not be ascertained for 4 of the 20 items of the CES-D scale because of the grouping of choices available to the respondent, we did not analyze these nondepressive items. We did not take race into account, since only 2% of the community respondents and none of the patients were black.

Percentages were adjusted to control for the effects of four demographic variables—age, sex, marital status, and education—by means of a binary variable multiple regression procedure developed by Feldstein (16) and modified by Dr. H. Abbey and Dr. J. A. Tonascia of the Department of Biostatistics, Johns Hopkins School of Hygiene and Public Health. This procedure requires a valid response for each of the 4 demographic variables and for each of the 16 CES-D items. Fifty-eight community respondents had incomplete responses, leaving 1,614 people in the analysis.

We assessed the significance of differences between inpatients and community residents by assigning confidence limits for each percentage (17, table 41). When the confidence intervals did not overlap, the two percentages were judged to be significantly different ($p \leqq .05$).

RESULTS

The adjustments to control for the 4 demographic variables resulted in very small changes in the percentages. The greatest absolute change was 3.6%, and most changes were within 6% of the unadjusted value.

Table 1 shows the adjusted percentages of community respondents and inpatients reporting the presence and persistence of the 16 symptoms of depression. A strikingly high percentage of both the community respondents and the nondepressed patients reported presence of 4 of 5 physiological symptoms. However, the percentage of depressed patients reporting presence of each of the 5 physiological symptoms was significantly higher than the community respondents. Among the 11 psychological symptoms of depression, all but 2 ("bothered by things" and "people were unfriendly") were significantly more common in the depressed patient group than the community group and 5 were reported by over 70% of the depressed patients. The psychological symptoms were generally less common among community respondents than the physiological symptoms; only 2 symptoms ("felt depressed" and "bothered by things") were reported by more than 30% of the respondents. In contrast to the physiological symptoms, the nondepressed patients reported 6 of the 11 psychological symptoms significantly more frequently than the community respondents and, for these symptoms, approached the rates of the depressed patients.

When persistence of symptoms for 5–7 days in the previous week is considered, a symptom-by-symptom comparison shows that the values for nondepressed patients are virtually identical with those for the community sample, whereas the values for the depressed patients are significantly higher than the community for all symptoms except "people were unfriendly."

TABLE 1
Community Respondents and Depressed and Nondepressed Inpatients Reporting the Presence and Persistence of 16 Symptoms of Depression, in Percents

Symptoms	Community Respondents (N=1,614)		Nondepressed Inpatients (N=15)		Depressed Inpatients (N=30)	
	Presence	Persistence	Presence	Persistence	Presence	Persistence
Physiological						
Had poor appetite	24	7	14	2	50*	34*
Had trouble concentrating	39	7	50	0	84*	57*
Couldn't get going	38	7	31	1	77*	34*
Felt everything an effort	47	18	59	16	88*	60*
Restless sleep	44	12	53	9	76*	35*
Psychological						
Talked less than usual	25	4	38	0	62*	31*
Felt like a failure	11	2	40*	0	59*	27*
Felt fearful	15	2	45*	7	72*	30*
Couldn't shake off blues	21	4	25	1	85*	40*
Felt people disliked me	12	1	26	0	56*	20*
Felt depressed	36	6	65*	7	88*	51*
Felt lonely	24	5	59*	1	84*	38*
Had crying spells	11	1	53*	0	47*	20*
Felt sad	29	4	58*	1	80*	40*
Bothered by things	37	5	64	7	47	30*
People were unfriendly	12	2	11	0	20	7

*This percentage is significantly different ($p<.05$) from the percentage of community respondents reporting this symptom.

Persistence of 5 of the 16 symptoms for 5–7 days was reported by 40% or more of the depressed patients.

DISCUSSION

One limitation of our data is that the patient groups were not randomly selected. The community group is a random sample, however, and comparisons among the groups can be made at a level of confidence that would hold if each patient group were a randomly selected group of the same size. The adjustment for the four major demographic variables removes some of the extraneous variation that can invalidate comparisons.

The data in table 1 confirm previous reports (7, 18, 19) of the relatively frequent occurrence of depressive symptoms among nondepressed inpatients and among community residents. However, the fact that the most frequently reported symptoms in the community group were concentrated in the physiological category (4 out of 5) suggests that the mere presence of these symptoms may be of relatively little value in the identification of significant levels of depression and that they may be associated with other conditions. The significantly more common presence of these 4 symptoms in the depressed group suggests that the depressive syndrome rarely occurs in the absence of these symptoms.

The data in table 1 suggest that presence of 6 of the psychological symptoms ("felt life a failure," "felt fearful," "felt depressed," "felt lonely," "had crying spells," and "felt sad") may be more indicative of general psychopathology than specific for depression. The presence percentages of these symptoms did not differ significantly between the two inpatient groups, but both inpatient groups had significantly higher presence percentages than the community sample. Furthermore, it seems that it is primarily the presence of these symptoms rather than their persistence that differentiates the nondepressed inpatients from the community population. In other words, nondepressed patients are more likely than the general population to have experienced these psychological symptoms of depression (but not the physiological ones) at some time during the week before the interview, but these symptoms have not been any more persistent than those experienced by the community respondents.

All symptoms except "people were unfriendly" were significantly more persistent among the depressed patients than the community respondents, while the latter had rates almost identical with the nondepressed patients. Therefore, the persistence of any of these symptoms for 5–7 days might be considered suggestive evidence for the presence of the depressive syndrome. This is especially so since it is assumed that a certain proportion of the community respondents, perhaps as many as 5–15% (19), were also depressed at the time of the survey and probably contributed to the percentage of community respondents reporting persistent symptoms. In particular, 3 symptoms, ("had trouble concentrating," "felt everything an effort," and "felt depressed") were reported to have persisted for 5–7 days by over 50% of the depressed patients and may be considered to be relatively necessary indicators of the depressive syndrome.

Two symptoms, ("bothered by things" and "people were unfriendly") were no more common among

the depressed or nondepressed patients than among the community respondents, and the symptom "people were unfriendly" was equally nonpersistent in all three groups; this finding suggests that neither of these symptoms contributes significantly to the overall assessment of depression or indicates the presence of general psychopathology.

Our findings, then, support the suggestion of Dohrenwend and Crandall (7) that evidence bearing on the duration and persistence of symptoms may be more significant than "sheer numbers of symptoms" in any assessment of depressive symptoms in patient or community groups.

Psychiatric Disturbances of Aged Patients in Skilled Nursing Homes

BY RUTH B. TEETER, PH.D., A.C.S.W., FLOYD K. GARETZ, M.D., WINSTON R. MILLER, M.D., AND WILLIAM F. HEILAND, M.B.A.

The authors found that 85% of 74 patients supported by Medicaid in two skilled nursing facilities had significant psychiatric disorders in addition to serious multiple medical illnesses. Almost two-thirds of the psychiatric disturbances had not been diagnosed. Although staff were more concerned with the psychosocial than the physical aspects of patients' problems in more than half of the cases, they often had difficulty recognizing the legitimacy of psychological complaints and relating to patients with psychological disturbances. Staff were not clear about the orders for psychotropic medications that were prescribed for more than half of the patients. The authors point out that more psychiatric consultation is needed to ensure appropriate and effective care for psychiatric patients in such facilities.

NURSING HOMES have become important sites for the care of psychiatrically impaired elderly individuals, apparently because of underutilization of outpatient facilities by the elderly (1, 2) and a trend in many states to reduce admissions of older patients to state mental hospitals (3). Thus the nursing home has inherited the psychiatrically ill older patient by default.

As early as 1962, Goldfarb (4) reported that 87% of patients in nursing homes had chronic brain syndrome. Redick and associates (3), quoting a recent report by the National Center for Health Statistics (5), noted that 53% (N=214,203) of patients over 65 in nursing homes in 1964 had psychiatric disorders. Redick and associates also noted that statistics on the prevalence of psychiatric disturbances in nursing homes were incomplete for more recent years.

Stotsky (6) reported that "on the whole, placement of psychiatric patients in nursing homes has been successful" but that this success depended on adequate screening, sensible treatment programs, and aftercare support by referring psychiatric facilities. Problems arise, however, when there is a lack of information from the referring facility (7).

Yudin and associates (8) found inadequate medical records in nursing homes and noted a need for more psychiatric consultation. Butler (9) believes that nursing homes are out of the mainstream of psychiatry and that psychiatrists are rarely available for consultation.

Our research was designed to shed light on 1) the current prevalence and nature of psychiatric disturbances of patients supported by Medicaid in proprietary skilled nursing facilities, 2) the quality of medical records in general and psychiatric records in particular, 3) staff attitudes toward patients, particularly those with psychiatric disturbances, 4) the nature and frequency of visits by significant others, and 5) the relationship of variables 2–4 to the nature and severity of the patient's condition.

METHOD

Two proprietary nursing homes in a midwest metropolitan area were selected for study. The homes were matched for average age of patients, average length of stay, socioeconomic level of patients, distribution of patients by sex, and percentage of Medicaid patients. The two homes had a total of 251 Medicaid patients in skilled nursing care. A random sample of 100 patients was selected. Of these, 26 were lost by attrition (8 died, 10 refused to participate in the study, 5 were transferred to other facilities, and 3 were under age 65). The remaining 74 patients were the subjects of intensive study. All patients, informants, and staff participants were requested to sign consent forms, and all refusals were respected.

Data-collection procedures were as follows:

1. Each patient was given a semi-structured interview protocol that included the short mental status questionnaire developed by Pfeiffer (10). The questionnaire, which contains 10 items that test memory and orientation, was scored as follows: 0–2 errors = intact intellectual function, 3–4 errors = mild impairment, 5–7 errors = moderate impairment, and 8–10 errors = severe impairment.
2. A responsible relative or significant informant of each patient was also given a semi-structured interview.

Dr. Teeter is Associate Professor, Center for Youth Development and Research, and Dr. Garetz is Professor, Department of Psychiatry, University of Minnesota Medical School, Box 393, Mayo Memorial Building, Minneapolis, Minn. 55455. Dr. Miller is Consultant for Medical Review, Minnesota Department of Health, Minneapolis, and Mr. Heiland is Statistical Consultant, International Time Sharing, Inc., Minneapolis. Address reprint requests to Dr. Garetz.

3. Nursing home personnel, including licensed staff and nursing assistants directly responsible for patient care, were interviewed regarding each subject.

4. Individual medical records were reviewed, assessed, and rated to determine diagnoses, therapies, course of treatment, and overall adequacy of the record.

5. Administrative and supervisory personnel were interviewed to determine overall organizational structure, personnel policies, philosophy of care, and implementation of procedures to assure quality of care.

6. Observational data were obtained on patient-staff interactions, staff relationships, ambience of residence, and stimulation and attractiveness of the physical environment.

One of the authors (R.B.T.), a social work clinician, conducted the interviews with patients, informants, and staff. Although this may have introduced the personal bias of the interviewer, any bias was assumed to be constant throughout the study. The medical chart review ratings and diagnostic classifications were determined by a psychiatrist (F.K.G.) and his assistant, a psychiatrist-in-training.

A primary psychiatric diagnosis (or a designation of "no psychiatric disorder") and one or more secondary diagnoses (if warranted) were made for each patient. Diagnoses were made only if there were clear and overt findings of sufficient magnitude to warrant a diagnostic label. For example, cognitive impairment thought to represent physiologic aging was not diagnosed as chronic brain syndrome. Similarly, unhappiness and dysphoria were not considered sufficient basis for a diagnosis of depression. Diagnoses were based on data from 1) interviews of patients, relatives, and staff; 2) direct observation of patients; and 3) medical records. A diagnosis was considered missed or incorrect when there was a disparity between the research psychiatrist's diagnosis and the data in the medical record.

RESULTS

Sample Characteristics

The mean age of the patients was 81.2 years, and the average age at admission to any nursing home was 79.3 years. Eighty percent were women, 91% were white, and 76% were in a nursing home for the first time.

The patients had many general medical problems—the average number of medical diagnoses per patient was 4.7. Fifty-nine patients (80%) had a diagnosis of cardiovascular disease, and 29 patients (39%) had a neurological disorder. A mean of 6.9 medications was prescribed per patient.

Thirty-two percent of the patients had histories of significant mental or emotional disorders. Of these, 21% had schizophrenic disorders, 33% had depressive disorders, and 17% had problems related to alcoholism. (These diagnoses were reconstructed from interview data and existing records.) Of those with a history of mental or emotional illness, over half had not received medical treatment for the previous condition.

TABLE 1
Distribution of Psychiatric Disorder, Cognitive Impairment, and Missed or Incorrect Diagnoses in 74 Nursing Home Patients

Item	Number	Percent
Psychiatric disorder	63	85.0
Chronic brain syndrome	34	45.9
Depression	19	25.6
Other	10	13.5
Missed psychiatric diagnosis	45	60.8
Incorrect psychiatric diagnosis	5	6.7
Moderate or severe cognitive impairment	44	59.4

Psychiatric Diagnoses

Sixty-three patients (85%) were given a primary psychiatric diagnosis. Of these, 34 had chronic brain syndrome, 10 without psychosis and 24 with psychosis. Thus 46% of the total sample of 74 patients had a primary diagnosis of chronic brain syndrome. Sixteen patients were given a primary diagnosis of depressive neurosis and 3 patients were diagnosed as having psychotic depression. The distribution of other primary diagnoses was as follows: schizophrenia, N=5; paranoid psychosis, N=2; anxiety neurosis, N=1; and personality disorder, N=2.

Thirty-nine patients (52.7%) were given a secondary psychiatric diagnosis and 5 patients were given 2 secondary diagnoses. The distribution of the 44 secondary psychiatric diagnoses was as follows: chronic brain syndrome, N=13; depression, N=18; schizophrenia, N=2; chronic alcoholism, N=5; and personality disorder, N=6.

When primary and secondary psychiatric diagnoses were considered in the aggregate, 47 patients (63.5%) showed chronic brain syndrome, 37 patients (50%) had depression, 9 patients (12.2%) showed schizophrenic or paranoid psychoses, and 5 patients (all men) had histories of serious alcoholism.

Missed and Incorrect Psychiatric Diagnoses

As table 1 shows, in 61% of the subjects (N=45) one or more psychiatric diagnoses were missed. One psychiatric diagnosis was missed in 22 of these patients and 2 in 23 patients. Missed diagnoses were as follows: depression, N=34; schizophrenia, N=5; chronic brain syndrome, N=13; and other, N=15.

Incorrect diagnoses occurred in only 5 cases. In 4 of these, the patient was diagnosed as having chronic brain syndrome, but the research team did not believe that this diagnosis was warranted.

Serious Diagnoses

By definition, patients in skilled nursing care are seriously ill. Our data highlight the severity of their condition and the complexity involved in their care due to the existence of multiple, serious diseases. "Serious

diagnoses" include both general medical and psychiatric disorders. If the condition was life threatening (e.g., cancer, severe heart disease, or severe chronic brain syndrome) or if it caused serious impairment (e.g., schizophrenia, advanced arthritis), it was labeled serious. Conditions such as mild hearing loss, less severe depressions, hernia, etc., were not so labeled. The research physician (F.K.G.) determined the number of serious diagnoses for each patient based on data from interviews and medical records. Patients had a range of 1–5 serious medical diagnoses, with a mean of 2.28. Thirty patients had 3 or more serious diagnoses, which invariably meant that their physical status and general medical situation was very grave.

Mental Status Questionnaire

On the mental status questionnaire, 16 patients showed intact intellectual function, 14 patients showed mild impairment, 12 patients showed moderate impairment, and 32 patients showed severe impairment. Thus almost 60% of the patients showed moderate to severe cognitive impairment, and 78% of the patients had some degree of cognitive impairment.

Use of Psychotropic Medication

Several important aspects of the use of the psychotropic medications in nursing homes emerged from this study. Forty-one patients (55.4%) received some kind of psychotropic medication—major and minor tranquilizers were used most often, with occasional use of antidepressants, vascular dilators, and cerebral stimulants or enhancers of cerebral metabolism. Psychotropic medications were prescribed on a regular daily basis for only 13 patients (17.6%). For 30 patients these medications were prescribed on an as-needed basis and the orders rarely gave the nursing staff a clear indication of the circumstances under which the medication was to be given.

For 11 patients, physicians ordered more than one medication in a particular class of medications (e.g., analgesics, hypnotics, or tranquilizers). These were as-needed orders without clear indications of the sequence or circumstances for giving the medication or of whether more than one was to be used. Nursing notes rarely documented the reason for the use of such medications and nurses generally expressed a lack of confidence in their understanding of the basis for giving the medications prescribed, particularly the tranquilizers.

Nurses' and Physicians' Notes

In 7 cases nursing notes were written every other day or more frequently. Notes were recorded less than every other day but at least once a week in 51 cases and less than once a week in 16 cases. In 44 cases, physicians made notes at least once a month (notes were rarely made more than once a month). Notes were made at least once every other month but less than once a month for 22 patients and less than every other month for 8 patients.

Adequacy and Correctness of Medical Records

The research physician subjectively rated records on a scale of 10–50 (10 = very poor, 50 = excellent) in terms of adequacy and correctness of records and diagnoses. Eight records were rated as excellent overall, 17 as good, 22 as fair, 17 as poor, and 10 very poor. Thus, over a third of the records were considered poor or very poor. Correctness of psychiatric diagnoses was rated good in 8 cases, fair in 21 cases, poor in 28 cases, and very poor in 11 cases (6 cases were not rated in this regard). Thus slightly more than half of the psychiatric records were rated poor or very poor.

Staff Attitudes

The first attitudinal variable investigated was the major concern of staff regarding each patient's current status. We found that staff were primarily concerned with patients' physical problems in 34 cases and with psychosocial aspects in 40 cases. The two other variables were rated by one of the authors (R.B.T.) on the basis of interview and observational data. Ratings ranged from 1 to 5, with 5 being most favorable.

Ratings of staff attitudes toward the legitimacy of a patient's complaints were distributed as follows: extremely positive, N=11; fairly positive, N=29; neutral, N=17; fairly negative, N=16; and extremely negative, N=1. Staff interactions with patients were considered very positive (i.e., appropriate and without infantilization) for 3 patients, positive for 26 patients, neutral for 10 patients, somewhat negative for 28 patients, and very negative for 7 patients. Again, in almost half of the cases, the staff showed negative or inappropriate attitudes (characterized in most cases by hostility and/or infantilization) toward their patients.

Informants

Extensive interview data were obtained from an informant, the most significant other person in the patient's life at that time who was capable of providing the desired information. Two informants were spouses, 34 were offspring, 34 were other relatives, and 4 were close friends of the patient.

The nature and frequency of visits by the informant varied considerably. The overall mean number of visits per month was 6.35; 7 informants visited less than once a month and 3 visited daily. Over two-thirds of the informants visited at least once a week. Half only visited, whereas the other half also did some personal things for the patient (e.g., grooming of hair).

Impact of Clinical Factors on Other Variables

Patients were divided into subgroups on 6 clinical classifications—type of psychiatric diagnosis, number of serious diagnoses, mental status score, area of major staff concern, use of psychotropic medications, and number of missed diagnoses. We then compared the subgroups' mean scores on the following variables: staff view of legitimacy of patients' complaints, appropriateness of staff-patient relationships, frequency of

TABLE 2
Means of Five Variables by Subclassifications

Classification	N	Variable: Staff View of Legitimacy of Complaints*	Staff-Patient Relationship**	Informant Visits per Month	Physicians' Notes per Year	Nurses' Notes per Year

*Rated on a scale of 1–5 (1=least legitimate, 5=most legitimate).
**Rated on a scale of 1–5 (1=most negative, 5=most positive).

informants' visits, physicians' notes per year, and nurses' notes per year. Table 2 presents the means for the first 5 variables listed and the statistical significance as determined by univariate analyses of variance.

As table 2 indicates, staff were more positive toward complaints of patients with no psychiatric disorders than those with psychogenic or organic psychiatric disorders. Staff were also significantly more positive in their attitudes toward patients' complaints and their interactions with patients when their concern was primarily with the patient's physical status. Staff relationships were more positive for patients with no psychiatric diagnosis or psychogenic diagnoses than those with organic psychiatric diagnoses. Furthermore, staff-patient relationships were more positive but physicians' and nurses' notes were less frequent for patients who had fewer than three serious diagnoses.

The only significant difference found in the comparison of patients with mental status scores of 5 or less and those with scores above 5 was that staff-patient interaction was more positive with patients who had less cognitive impairment. No significant differences were found in analyses based on use of psychotropic medication or number of missed diagnoses.

CONCLUSIONS

Our study documents the fact that over three-quarters of patients in skilled nursing homes have a diagnosable psychiatric condition, yet nursing personnel are uncomfortable with psychological disturbance in their patients and not well educated in most aspects of diagnosis and treatment of psychiatric conditions. At the same time, most physicians who attend nursing homes do not maintain adequate psychiatric records, use psychotropic drugs in an optimal way, or respond to worsening psychiatric conditions with more frequent visits.

These conditions of care are unacceptable. They can be improved if psychiatrists would be willing to 1) become more involved as consultants to nursing homes, 2) involve themselves more with inservice training for nursing staffs and postgraduate training of physicians in nursing homes, and 3) advocate and participate in increased emphasis on geriatric psychiatry in the curricula of all health science professional schools. Accomplishing these objectives is a challenge that psychiatrists can no longer ignore.

Clinical Depression Among Narcotic Addicts Maintained on Methadone in the Community

BY MYRNA M. WEISSMAN, PH.D., FRANK SLOBETZ, BRIGITTE PRUSOFF, M.P.H., MARJORIE MEZRITZ, M.A., AND PAT HOWARD, R.N.

In a study of 106 predominantly young, lower-social-class men participating in a methadone maintenance program, the authors found that about one-third were moderately to severely depressed as assessed on standard rating scales of depression. The depressive symptoms were associated with a decrease in social functioning, increase in stress in the past 6 months, and a history of alcohol abuse. Because the combination of depression and drug addiction creates a high risk for suicide, depressive symptoms require early detection and treatment. The authors point to the need for more research on treatment approaches, particularly the use of psychotropic drugs.

THE PRESENCE of depressive symptoms in opiate-addicted individuals has received clinical mention (1–3) but little systematic study. This lack of attention may be due to the fact that depression in these patients presents both diagnostic and treatment problems. Diagnostically, it may be difficult to differentiate the symptoms of depression from the side effects of opiate use or withdrawal. This is particularly a problem when the addict is being maintained on the synthetic opiate methadone hydrochloride during treatment. Even if this differentiation can be made, there is no consensus as to how to treat secondary depression in a patient with another, primary psychiatric problem.

Interest in depression in the individual receiving methadone maintenance treatment for opiate addiction is more than academic since the presence of depressive symptoms can contribute to the use of compensatory outlets, to higher attrition, and to difficulty in discontinuing methadone. For example, in a conversation Kleber noted that the depressed methadone patients enrolled in the New Haven Connecticut Mental Health Center Methadone Maintenance Program overuse alcohol and other drugs and overeat or chain-smoke and that patients who develop depressive symptoms during detoxification from methadone have higher rates of attrition and failure.

Aside from a recently completed study by Senay (4), which included a survey of depressive symptoms in patients entering methadone maintenance treatment at the Illinois Drug Abuse Program, we could not find any formal studies on the subject. This paper will report the results of a survey that examined the frequency and nature of depressive symptoms and social functioning in a cohort of methadone-maintained patients. This is the first report of an ongoing

longitudinal study in which we will examine the course of the symptoms as part of an effort to develop treatment strategies for subgroups of drug-addicted individuals.

METHOD

Methadone Program

The Methadone Maintenance Clinic of the Drug Dependence Unit, Connecticut Mental Health Center—Yale University was founded in 1968 for the purpose of rehabilitating hard-core addicts. The program consists of methadone maintenance on an outpatient basis used in conjunction with a variety of psychosocial supports and with high patient involvement in running the program (5, 6). Patients are usually either self-referred or referred from the courts or parole board. There are over 150 new admissions per year, and about 325 patients are in treatment in any 1 year. To be eligible for methadone maintenance a patient must have a history of at least 2 years of addiction to an opiate. About one-third of the patients have histories of more than 5 years' addiction.

Sample

The sample was selected from the Methadone Maintenance Clinic. The 106 patients selected included 62 consecutive first admissions and 44 patients who had been in maintenance treatment for an average of 1 year. All patients included in the study had agreed to participate after the nature of the procedure was fully explained to them and had signed consent forms before the interview. Since the differences in sociodemographic and clinical characteristics between the 2 patient groups were within chance expectation, the data from both samples have been combined.

Assessment

Basic sociodemographic, psychiatric, and drug history information was collected. Clinical status was assessed by clinician's rating and by patient self-report. Clinician rating included the Raskin Depression Scale (7) and the Hamilton Rating Scale for Depression (8). Self-report data were collected on the Hopkins Symptom Checklist (9). Social functioning over the past 2 months was assessed on the Social Adjustment Scale (10). A semistructured interview was used to obtain information on the occurrence of 61 life events, spanning a wide range of experiences in the past 6 months (11). All instruments were selected because of their prior use with depressed outpatients, and they were pretested in an addict population before the beginning of the survey to determine their suitability for this population.

A master's-degree level rater who had considerable experience with nonaddicted depressed outpatients conducted all of the interviews. She underwent a period of training and testing for interrater reliability with a psychiatrist and received training in interviewing drug addicted individuals before undertaking the formal survey.

RESULTS

Sociodemographic Characteristics

The patients were predominantly young (mean age=27), male (75%), white (53%), Catholic (49%), and from the lower social classes (81%) (12). Thirty-three percent were single and 30% were currently married; 54% had children. Most of the patients lived with a family member; only 15% lived alone. Geographic mobility was high: only 19% had lived at their present address for more than 2 years. Only 25% were in full-time employment. Educational level varied; 17% had had some college but 57% had not completed high school. Seventy-five percent of the patients came from a family headed by the father, and almost all of the patients (95%) were born in the United States. In sociodemographic characteristics, these patients were similar to the rest of the methadone clinic population.

Family and Patient Psychiatric History

A substantial number of the patients (64%) reported a history of mental illness in their parents or siblings, usually depression in the mother (14%) or alcoholism in the father (12%). Fifty-four percent of the patients themselves had had psychiatric treatment in the past, and of this group, 24% reported that they had received treatment before their addiction problem. Forty percent of the patients reported excessive alcohol abuse in the past.

Symptom Status

Table 1 illustrates the patients' degree of overall depressive symptoms based on the Raskin Depression Scale, which measures the patient's verbal report, behavior, and secondary symptoms of depression. A score of 7 or higher is usually considered to indicate depression of sufficient intensity to require antidepressant medication and is a criterion used for patients' admission to many clinical trials of antidepressant agents. According to the Raskin criteria, 32% of the patients were clinically depressed.

Comparison of Depressed and Nondepressed Patients

Social history. We next compared the sociodemographic and historical characteristics of the 34 depressed patients (scores of 7–12 on the Raskin scale) and the 72 nondepressed patients (scores of less than 7 on the Raskin scale). There were no significant differences in any of the variables, with the exception of alcohol use. The depressed methadone patients more frequently had a history of alcohol abuse ($p<.05$, chi-square test for categorical variables and t test for continuous variables). It is interesting that the 2 groups

TABLE 1
Degree of Overall Depressive Symptoms in 106 Methadone Patients

did not differ on duration of heroin abuse or on type of drug used.

Clinical symptoms. Table 2 compares the depressed and nondepressed patients on clinical symptoms as judged by the clinician and by the patient's self-report. As can be seen, the patients meeting the Raskin scale criteria for depression were significantly more symptomatic on most items. These findings were also reflected in their self-report ratings.

Social functioning. The depressed patients showed more impairment in social role functioning (see table 3). These differences failed to reach statistical significance in work, marital, and parental roles, in which a substantial number of methadone patients could not be rated.

Stress. We also examined differences between the depressed and nondepressed patients in life events during the previous 6 months. The depressed patients had experienced a significantly higher total number of events and perceived the events as more stressful ($p<.05$, t test).

The two individual events that had occurred significantly more frequently in the depressed patients were "major physical or emotional illness of family members not leading to death" (present in 41% of the depressed patients and only 15% of the nondepressed patients) and "increase in arguments with spouse" (21% and 6%, respectively) ($p<.05$, t test). The latter finding is of particular interest because it is the most powerful item that distinguished a depressed cohort from a community control group (11).

DISCUSSION

In our study of predominantly young, American-born, lower-social-class men who were drug addicts in a methadone maintenance program, we found that about one-third were moderately to severely depressed. Their symptoms included disturbance of

mood sleep, appetite, and sexual functioning, accompanied by anxiety and suicidal feelings. The depressive symptoms were associated with a decrease in social functioning, increase in stress in the past 6 months, and a history of alcohol abuse.

It is not possible to predict which population of drug addicts under treatment will be depressed; the presence of the depression in this sample was not related to the patients' sex, race, social, drug, or psychiatric history.

Is This Really Depression?

Drug addicts can present a special diagnostic challenge since depressive symptoms may be attributed to physiological symptoms of withdrawal or to the apathy or anomie of a deviant lifestyle. There may be a question as to whether the patients in this study were really clinically depressed or whether the depressive symptoms represented the consequence of being in a state of withdrawal from heroin or of being maintained on methadone.

In regard to the effects of withdrawal, disturbed sexual functioning, anxiety, and appetite disturbances have been reported in narcotic addicts who are being withdrawn (13, 14). However, this explanation seems unlikely for our group since the newly admitted patients were not in withdrawal and the remaining 40% were already stabilized on methadone when interviewed. Regarding the possibility that methadone itself produces symptoms, a recent report by Gritz and associates (15) indicated that methadone does not have noticeable physiological effects.

We feel the evidence suggests that these patients were indeed clinically depressed, for the following reasons. We used multiple criteria for diagnosing depression. Patients were only considered depressed if they met the criteria of verbal report, behavior, and secondary symptoms. They were not included if they only reported mood disturbance or only reported secondary symptoms without the disturbed affect. When the methadone patients who met the 3 criteria for depression on the Raskin Depression Scale were compared with those who did not, the depressed patients were judged by both the clinician and themselves as significantly more symptomatic and more socially impaired.

We found that approximately 30% of the patients met the criteria for depression, a figure quite close to the rate of 20%–25% that Senay (4) found among 190 patients who were entering the Illinois Drug Abuse Program and were assessed on the Beck Depression Inventory (15) and the Hamilton rating scale (8).

Further confirmatory evidence could come from a double-blind controlled clinical trial of tricyclic antidepressants versus placebo randomly assigned to determine if this subgroup of depressed addicts responded to active medication.

Secondary Depression and Its Treatment

Robins and Guze have attempted to reduce the heterogeneity of depression by distinguishing primary from secondary depression (17). To justify a diagnosis of depression a patient must first have a dysphoric mood, a predetermined number of somatic and psychological symptoms, and a definite onset. When a depression meets these criteria, its classification as primary or secondary depends mainly on chronology and the presence or absence of various other psychiatric disorders.

In our drug-addicted population it was difficult to determine if the depression preceded or followed the addiction. Given the long history and severity of their addiction, the depressed patients in this study would most likely be considered as having secondary depression. While the distinction between primary and secondary depression is useful for research purposes, the validity of this distinction still awaits further data from follow-up, family, and laboratory studies. Moreover, it is unclear if their treatments differ.

While there is good evidence that tricyclic antidepressants are effective in the treatment of the acute symptoms of primary depression, there is less clarity as to their value in treating secondary depression. In practice, primary and secondary depressions usually receive similar treatment, although this procedure is based on little experimental data. The absence of data in opiate-addicted patients is striking, since these patients are usually excluded from clinical trials of psychopharmacological agents.

In our review of the literature we found only one randomized, double-blind placebo-controlled trial of antidepressant agents in a homogeneous sample of depressed methadone-maintained subjects. Woody and associates (18) reported preliminary results from a 16-week placebo-controlled trial of doxepin in 35 methadone patients with some depressive symptoms. This was a pilot study and requires replication since only men were included and the sample was small. However, their data did show that patients receiving doxepin felt less depressed and also had a decrease in amphetamine abuse. No adverse reactions were found between doxepin and methadone.

While controlled psychopharmacological trials have been lacking, there have been a few open trials and clinical reports. Altamura (3) reported results from an open trail of lithium carbonate with 20 opiate addicts unselected for affective symptoms. Although the investigator felt that some patients reported a decreased psychological dependence on illicit drugs while receiving lithium carbonate, no conclusions could be drawn because of the study design and poor patient compliance. In a retrospective clinical study, Tislow (19) found that depressed patients in methadone programs responded favorably to psychotropic drugs, as evidenced by increased social and clinical well-being and reduced attrition and treatment failure. Kaufman and Blaine (20) noted that imipramine successfully alleviated depression in methadone patients but that results were not always consistent. This review of the available literature highlights the relative absence of research in this area.

CONCLUSIONS

Our findings, consistent with the reports of the Senay group in Chicago, indicate that a substantial minority of methadone maintained patients are clinically depressed as assessed on standard rating scales of depression. However, in generalizing the findings it should be stressed that the patients studied were predominantly young, white, and Catholic and, as such, may be different from typical opiate addicts, although not necessarily different from the sample of persons treated with methadone maintenance.

The combination of depression and drug addiction, which in this sample was frequently associated with alcohol abuse, creates a high risk for suicide. Because of this risk, depressive symptoms require early detection and special treatment in the addict population. Some evidence suggests that the reduction of the secondary symptoms of depression with psychotropic drugs may offer an additional therapeutic modality. Our treatment experience with primary depressives indicated that psychotropic drugs would need to be coupled with the usual rehabilitative psychotherapeutic approaches of drug treatment programs (21, 22).

However, the treatment of most secondary depressions requires considerably more attention, particularly to the testing of psychotropic drugs in controlled clinical trials. These data are especially lacking as guides to the treatment of the depressed opiate addicted patient.

Rate of Psychiatric Morbidity in a Metropolitan County Jail Population

BY JOHN PETRICH, M.D.

The author describes social-psychiatric characteristics of 122 jail inmates examined while awaiting trial, 80% of them on felony charges. The estimated overall rate of psychiatric illness was 4.6%. The patient sample was significantly older and contained significantly more minority group men than the jail population as a whole. Thirty-six percent of the patients diagnosed as schizophrenic were arrested on misdemeanor charges. Drug dependency was diagnosed in 51% of the men but in only 15% of the women. Psychosis was diagnosed more frequently and alcoholism, anxiety neurosis, and antisocial personality less frequently than in studies of prison populations using similar diagnostic criteria.

LOCAL JAIL FACILITIES have been used since colonial times to confine mentally disordered persons (1). The incorporation of psychiatric treatment programs into metropolitan jails is relatively uncommon. In a 1973 study by the American Medical Association, only 13% of the nation's jails surveyed reported they had psychiatric services for mentally ill inmates (2). Yet law enforcement personnel (3) and jail medical staff (4) consider psychiatric illness to be the single major health problem among inmates in metropolitan jails.

A psychiatric consultant has been available to the King County Jail, Seattle, Wash., since July 1972 to provide in-jail psychiatric treatment and referral services to the inmates. This paper offers an estimate of the psychiatric morbidity in this jail and describes the characteristics of the inmates. It illustrates some important differences between the psychiatric morbidity of the jail population and that of other offender groups who have been studied. Unusual features of this study are the sampling of a modern metropolitan jail inmate population and the use of explicit diagnostic criteria that have been used with other offender populations, making limited comparisons possible. The data were compiled during a 5-month survey from September 1, 1973, through January 31, 1974.

Dr. Petrich is Assistant Professor of Psychiatry, Department of Psychiatry and Behavioral Sciences, ZA-10, University of Washington, Harborview Medical Center Campus, 325 Ninth Ave., Seattle, Wash. 98104.

THE SETTING

The King County Jail provides detention facilities for all individuals jailed on felony charges in the county (population 1,100,000) and for those jailed on misdemeanor charges from the area of the county outside the Seattle city limits (approximately 600,000 people). A total of 6,510 men and women were booked into the King County Jail during the 1974 calendar year, the last year for which such data are available. The jail has a capacity of 525; the average daily census for 1973 was 271 inmates. Two-thirds of the inmates are held for an average of 30 days while awaiting trial, and one-third are held for an average of 120 days while serving sentences. The King County Jail provides adequate physical space and sanitary and kitchen facilities and is staffed by trained personnel with high morale.

Members of the King County Sheriff's Department are responsible for the administration and security operations of the jail facility. The Seattle King County Department of Public Health provided medical and psychiatric services to the jail on a contract basis.

The goals of the psychiatric consultant are to provide in-jail psychiatric treatment and referral services for inmates and ongoing psychiatric treatment for those inmate-patients who must remain in the jail for prolonged periods. The issues of legal sanity and competency to stand trial are not addressed; referrals regarding these matters continue to be directed to private practice psychiatrists.

METHOD

While no formal attempts were made to screen all inmates for psychiatric illness, all segments of the jail staff—custody officers, social service personnel, and medical staff—referred patients. These individuals had some daily contact with every jail inmate and were in a position to identify those with psychiatric illness. It was common for patients to be identified by the custody officers at the booking desk.

All referrals were screened by the same half-time psychiatrist (J.P.). Those patients not evaluated were judged to need no psychiatric evaluation or left the jail before they were examined. The psychiatrist administered a standardized interview format, which elicits data on demographic characteristics and drug, psychi-

atric, and criminal histories, and a standard diagnostic battery (5) to each patient examined. No attempts were made to verify inmates' criminal or psychiatric histories using court or hospital records.

For the purposes of this study, a "patient" is defined as any inmate who presented with a suspected psychiatric illness during the period of that particular booking in the jail. Patients who were released to the community and subsequently rearrested and rebooked during the study period and who required treatment again were counted as new patients. Patients who were treated and who experienced another episode of illness without having been released from jail were only counted once.

RESULTS

Patients Examined

In the 5-month period under study, 122 individual patients (102 men and 20 women) were examined by the psychiatrist out of an estimated 200 referrals. A number of individuals were referred for treatment but were released from the jail prior to examination or were judged to need no psychiatric examination. No data were compiled on these individuals, and there is no information on their characteristics relative to those of the patients who were examined and the jail population as a whole. In that same period the psychiatrist reported a total of 337 patient contacts, for an average of 2.75 contacts per patient. A total of 117 individuals was seen only once, and 5 individuals were seen twice. Over one-third of the inmates who were examined were identified and evaluated in the first 24 hours after booking. For those examined, fighting, suicide attempts, and other grossly disorganized and disruptive behavior precipitated referral in almost one-half of the cases (6).

The computation of accurate morbidity rates is difficult because in the 1973 calendar year data were not compiled on the number of individuals booked into the jail. The number of individuals booked in 1973 (N=6,300) was computed as the average of the number of individuals booked for calendar years 1972 (N=6,090) and 1974 (N=6,510). Review of data from 1972 through 1974 indicated a relatively consistent rate of jail bookings, with $^{5}/_{12}$ of all bookings for the year occurring during the 5-month study. Based on this figure, it was estimated that 2,625 individuals were booked into the jail during the 5-month study period. Based on the number of patients examined by the psychiatrist, it was estimated that the overall population had a psychiatric morbidity rate of 4.6%.

Demographic Characteristics

The patient group was significantly different from the overall jail population in two respects. The patient sample was older (mean of 31.0 years for men and 30.3 for women versus mean of 23.3 for men and 29.2 for women overall); it also had a higher percentage of minority group men (25% versus 11%) ($p<.001$, two-way analysis of variance). Nearly 75% of the male patients (N=69) and over 50% of the female patients (N=10) had never married or were divorced or separated.[1] Fifty percent of the male patients (N=45) and 43% of the female patients (N=7) had not graduated from high school.

Criminal History

Eighty percent of both the male and female patients (N=80 and 16, respectively) were booked into the jail on felony charges. The rest of the patients were charged with misdemeanors. The overwhelming majority of the male patients (N=83, or 89%) and almost three-quarters of the female patients (N=13) had a history of prior arrest with jailing. Less than one-half of the male patients (N=34, or 40%) and only 11% of the female patients (N=2) had served prison sentences.

Psychiatric History

A majority of the patients of both sexes reported that they had had prior psychiatric examinations (see table 1). These examinations included single examinations for court or welfare purposes as well as ongoing treatment regimes. Most of these patients had had psychiatric hospitalization, primarily in state hospitals. A number of the male patients had received inpatient treatment in military hospitals or in Veterans Administration hospitals. Considerably more men than women had received court-ordered psychiatric examinations. These examinations occurred while the subject was in a hospital, an outpatient, or in jail. A large number of the male patients had received psychiatric examinations while in jail or prison, compared with only one female patient. Most of the female patients reported suicide attempts, compared with less than one-third of the male patients.

Psychiatric Diagnosis

Table 2 summarizes the diagnoses of these 122 patients. Secondary depression was a common diagnosis and was often accompanied by agitation and suicidal ideation. The functional psychotic diagnoses of mania and schizophrenia were much more common among the male patients than the female patients. Of the 36 patients diagnosed as schizophrenic, 13 (36%) were jailed for misdemeanor offenses.

Antisocial personality was diagnosed in over one-third of the patients. The single diagnosis of antisocial personality was made in 4 patients. Twenty-four of the patients with this diagnosis also received a second diagnosis of drug dependence or alcoholism. Over one-quarter of the patients received a diagnosis of alcoholism. Drug dependency was a much more common diagnosis in the male patients than the female patients and was present in over one-third of the sample.

[1]These and other percentages reported in this paper are calculated on the basis of the number of inmates for whom information was available.

TABLE 1
Psychiatric History of 110 Psychiatric Patients in King County Jail, Seattle, Washington*

Item	Men (N=94) Number	Men (N=94) Percent**	Women (N=16) Number	Women (N=16) Percent**

*Total adds up to more than 100% because some subjects received more than 1 diagnosis.

DISCUSSION

Because no systematic attempt was made to screen all inmates for psychiatric disorder, the morbidity rates can only be considered as first approximations of the actual psychiatric morbidity. The calculated morbidity figures are probably low due to the fact that only 122 of the estimated 200 referred patients were actually examined. Data on those referred for examination but screened out by the psychiatrist or released before the examination were not compiled as part of the study, and no discussion of these individuals is possible. Lack of precision in the rates is compounded by uncertainty as to the actual number of inmates in the jail and at risk during the study period.

No systematic attempt was made to review court or hospital records to verify the patients' histories. Incidental verification frequently occurred from contact with families, therapists, or attorneys. Some distortion in the histories was evident, with patients frequently minimizing the extent of their criminal and psychiatric histories.

There was no clearly defined level of disability that resulted in psychiatric referral. The magnitude of disability ranged from dysfunction associated with assaultive or suicidal behavior to milder disturbances such as anxiety states and depressions. It is also likely that disruptive inmates were most frequently referred and that these patients are overrepresented in this sample (6).

The older mean age of the patients (31.0 years for men and 30.3 years for women) relative to the overall population is worthy of note. In his survey of large populations, Hagnell (7) reported that the average annual incidence of moderate to severe mental illness has a bimodal distribution, with peaks in the fourth and eighth decades of life. The average age of the jail patient population is in keeping with this trend. A relatively younger age of the overall jail population is in keeping with Robins' observation (8) that the peak period of severe disturbance is in late adolescence and early adult life and that the severity of the syndrome diminishes by the fourth decade.

The high proportion of patients who were unmarried or separated, had not completed high school, had prior jail and prison histories, and had prior psychiatric illness suggests that the typical in-jail psychiatric patient suffers from a generalized psychosocial disorganization. Most of these patients correspond to the group 3 patients identified by Yarvis (9) in his study of federal prison inmates. Those offenders were characterized by multiple prior convictions; poor work, military, and school performance; and a high frequency of psychiatric illness. These data indicate that the overwhelming majority of the jail patients would be classified as belonging to social class V of the Hollingshead and Redlich index of social position (10).

The high percentage of schizophrenic patients arrested on misdemeanor charges points to significant gaps in the psychiatric health services available to these severely handicapped individuals. The criminal activity of these patients may be viewed as only one manifestation of a total psychosocial disability and supports the concept that the jail is an important link in

the network of social support services for lower-class individuals (11).

It is difficult to establish accurate psychiatric morbidity data and prevalence rates for the various psychiatric syndromes in offenders. The offender population encompasses a wide diversity of problematic individuals who come to the attention of the criminal justice system. The class of offenders includes individuals who are involved in relatively minor antisocial actions (misdemeanors) as well as those who are involved in more serious antisocial behavior (felonies).

Guze and associates (12) have pointed out that selection forces operate at every step in the criminal justice system and accurate epidemiological studies become difficult. While most serious offenders are jailed pending trial, many are released on personal recognizance or bond. Not all offenders are found guilty of the offenses that they may have committed. Many plead guilty to lesser charges with the concurrence of the prosecution and the court to expedite the adjudication process. Others are found incompetent to stand trial or criminally insane. The disposition of these various offenders runs the gamut from probation to imprisonment, to state and local hospitals, as well as special supervisory situations.

Literature on the psychiatric morbidity of nonhospitalized offenders is scant and refers to the following 3 major offender groups: felons incarcerated in state or federal prisons, felons on probation or parole, and accused individuals held in jail (13).

IMPRISONED FELONS

More epidemiological data are available on the psychiatric problems of prison inmates than for any other offender group. Haines (14), Glueck (15), and McCartney (16) examined consecutive series of new admissions to state prisons. The prevalence of psychiatric abnormality reported (psychotic and neurotic conditions exclusive of psychopathy) varied from 12% in Glueck's study to 20% in Haines's and 28% in McCartney's. In a survey of psychiatric morbidity in over 20 prison psychiatric units across the nation, Anderson (17) reported rates of "nervous or mental abnormality" ranging from a low of 34% to a high of 82%. In a more recent attempt to measure the prevalence of psychiatric disorder in prison felons, Sutker (13) used a cross-sectional survey and the Minnesota Multiphasic Personality Inventory as a diagnostic tool. He reported that rates of psychoses, varying according to sex and race, ranged from 10% to 22%. These studies tell us little, however, regarding the clinical need for psychiatric treatment for these patients.

Other authors have reported morbidity data for prison inmates who require in-prison treatment. Ernst and Keating (18), in their descriptive analysis of the psychiatric treatment of California felons, estimated that 10% of prison inmates require segregation because of psychiatric illness. In a cross-sectional survey of inmates at Lewisburg Federal Prison in Pennsylvania, Roth and Ervin (19) reported that only 13% had ever received in-prison psychiatric treatment.

In spite of the varying and often unspecified criteria used for the diagnosis of psychiatric illness and the extreme range of reported rates of abnormality, one can say that from one-tenth to one-third of all prison inmates manifest psychiatric illness.

Direct comparisons of the jail-derived morbidity data with the prison data are unwarranted due to the differences in the populations studied. One might anticipate that the jail population, which contains individuals who will be adjudged either criminally insane or incompetent and individuals who are most acutely exposed to the stresses of total institutional living (20), would have even higher rates of psychiatric illness requiring treatment. It is my clinical impression that significant amounts of manifest psychiatric illness are as yet unrecognized in this jail's population, and that with more intensive case finding efforts, rates comparable to those reported for the imprisoned felons would be demonstrated.

NONINCARCERATED FELONS

Guze and associates (12, 21, 22) and Cloninger and Guze (23, 24) of the Washington University group in St. Louis used a standard psychiatric diagnostic battery to determine psychiatric morbidity rates among nonincarcerated felons. They found higher than average rates of antisocial personality, alcoholism, and drug dependency among men and women and of hysteria among women. Their study populations consisted of consecutive felons, and no attempt was made to select the subjects on the basis of manifest psychiatric disorder. The rates of schizophrenia ranged from 1% to 1.5%. No other psychotic illnesses were noted in their patient populations. Overall morbidity rates ranged from 52% to 81% exclusive of the diagnosis of sociopathy. Follow-up studies (21, 24) have confirmed their original assessments.

In spite of significant selection factors operative in the identification of the jail patients, the diagnostic schema for this study was similar to that used by the Washington University group, and limited comparisons can be made. Table 3 presents the diagnostic profile for convicted male and female felons studied by Guze and associates and Cloninger and Guze Certain differences between their study populations and the jail sample are evident. Jail patients had a higher rate of schizophrenia; in addition, the men had higher rates of drug dependency and mania and the women, primary depression. Alcoholism, anxiety neurosis, and antisocial personality were diagnosed less frequently in the jail patient population.

Many patients identified in the jail study would not have been included in the surveys by the Washington University group. Significant numbers of the jail patients who were charged with misdemeanors would

TABLE 3
Psychiatric Diagnosis of 289 Convicted Felons, in Percents

Diagnosis	Men (N=223)*	Women (N=66)**
Depression	—	6.0
Mania	—	—
Secondary depression	—	—
Schizophrenia	1.0	1.5
Anxiety neurosis	12.0	11.0

**Data are from Cloninger and Guze (24).

never have gone to prison or been referred to the state probation department. The felons were sufficiently handicapped that a large portion of them would have been sent to the state hospital for the criminally insane or other psychiatric hospitals or would have been judged incompetent to stand trial. A full understanding of the relationship between criminality and psychiatric disorders is not possible without studying this group of patients.

JAIL MORBIDITY

The famous "court clinics" of Boston, New York, and Chicago were established in the early part of the 20th century to assist local courts in the disposition of mentally disordered offenders. In an excellent review of then current programs, Anderson (17) reported a 45.6% overall prevalence of "abnormal mental conditions" in 1,000 presumably consecutively selected misdemeanants at the Municipal Court of Boston. In a series of reports Anderson (17, 25, 26) examined the prevalence of psychiatric morbidity in selected misdemeanant offender groups. He noted a wide range in prevalence; for example, 90% of the vagrants, 66% of the shoplifters, and only 48% of the prostitutes were regarded as mentally abnormal.

Bromberg and Thompson (27) reported markedly lower rates of psychiatric illness in their study of 10,000 consecutively selected cases of mixed misdemeanants and felons from the New York City Court of General Sessions. Eighteen percent of the sample was characterized by psychiatric abnormality, with 1.5% diagnosed as psychotic and 2.4% as mentally defective. They concluded from their study that "psychoses, mental defect, and psychopathic personality play a relatively minor role in the causation of crime."

The overall morbidity rates from this jail sample are more consistent with those reported by Bromberg and Thompson, suggesting that psychiatric morbidity in a mixed felon-misdemeanant jail population is under 20%. The relatively low psychiatric morbidity rates reported in this study may reflect the fact that the program's goal was to evaluate only problematic inmates for in-jail treatment. It is presumed that only a fraction of those reported as "abnormal" in the previously discussed studies would actually require in-jail treatment. Anderson's work does point to a relatively high rate of psychiatric illness found in the jailed misdemeanant. His observations were confirmed in the present study, where misdemeanants were overrepresented in the schizophrenic patient population (36% compared with only 20% in the overall jail patient population).

The impact of a psychiatric consultant in the jail on the jailing practices of the police and courts, as well as on the utilization of psychiatric services by inmates and staff, is poorly understood. At the time of this study the existence of the in-jail psychiatric program was not widely known, and it was unlikely that significant numbers of patients were jailed primarily for psychiatric treatment.

Psychiatric treatment is an important element in the overall care and rehabilitation programs for offenders. Until reliable morbidity data for the various subgroups and populations of offenders can be obtained, the development of programs and delivery of effective services will be inadequate.

Prompt Publication Policy

The *Journal* would like to remind authors who are particularly interested in early publication (whether to establish priority of an idea, reveal innovative results of new research, or for other pressing reasons) of its prompt publication policy. Under this policy, short (maximum of six double-spaced pages) manuscripts will be considered for publication in the Brief Communications section of the first available issue. These manuscripts must still undergo expert scrutiny before being accepted, and two months must be allowed for the printing process. However, the time required for publication of these short articles can be lessened considerably.

Authors who would like to have their manuscripts considered under this policy should indicate this desire, as well as the reasons for it, when they submit their manuscripts.

BRIEF COMMUNICATIONS

Mania and Schizo-Affective Disorder, Manic Type: A Comparison

BY RICHARD ABRAMS, M.D., AND MICHAEL ALAN TAYLOR, M.D.

The authors report data gathered from a consecutive sample of 88 psychiatric inpatients who were diagnosed as having either manic disorder or schizo-affective disorder, manic type, according to Research Diagnostic Criteria *(1) similar to those proposed for* DSM-III. *There were no differences between diagnostic groups on clinical psychopathological or demographic variables, individual or family history, or treatment response.*

KASANIN introduced the term "schizo-affective psychosis" to describe a group of patients he felt were atypical but who had a good outcome and an intact affect:

> These are fairly young individuals, quite well integrated socially, who suddenly blow up in a dramatic psychosis and present a clinical picture which may be called either schizophrenic or affective, and in whom the differential diagnosis is extremely difficult. (2, p. 99)

Although most clinicians would agree that some patients display a "mixed" clinical picture, the entity has yet to be validated. Clayton and associates' follow-up data (3) showed that schizo-affective disorder was related to affective disorder and not to schizophrenia. Post (4) was unable to define the condition as it occurred in late life as either a separate entity or a specific variant of either schizophrenia or affective disorder. Cohen and associates (5), in their study of 15,909 veteran twins, found that the monozygotic pairwise concordance rate for schizo-affective disorder was more than twice that for schizophrenia but did not differ from manic-depressive illness. Welner and associates (6) and Croughan and associates (7) reviewed the difficulties with prior research in the area and in their own record review were unable to define the relationship between schizo-affective disorder and schizophrenia or affective disorder. Recently, Sovner and McHugh (8) reported that 50% of a sample of patients with schizo-affective illness ran a bipolar course: they concluded that most such patients actually suffered from manic-depressive illness.

DSM-II, the current *Diagnostic and Statistical Manual of Mental Disorders* of the American Psychiatric Association (9), includes a subgroup of schizophrenia designated schizo-affective type but states only, "This category is for patients showing a mixture of schizophrenic symptoms and pronounced elation or depression." *DSM-III*, the proposed revision of *DSM-II*, is now under active discussion and is slated for publication in final form in 1978 (10). *DSM-III* will contain a separate section on schizo-affective disorder, with well-defined, objective diagnostic criteria. Preliminary formulations of these criteria have been distributed by Spitzer and associates as the *Research Diagnostic Criteria (RDC)* (1). The *RDC* have not been proposed as the final form of *DSM-III*—rather, it is understood that modification and revision will occur over time to accommodate the particular needs of an official manual, widely used for other than research purposes.

We wish to contribute to this process by providing some data relevant to the validity of the diagnostic criteria for schizo-affective disorder, manic type, as set forth in the second edition of the *RDC* and the working draft for *DSM-III* (11). Our study compares this diagnosis with that of manic disorder in a sample of patients diagnosed according to objective, specific criteria that are compatible with the *RDC*.

METHOD

The data are derived from a larger study of 247 patients admitted to an acute treatment, adult, general

Dr. Abrams is Professor and Vice-Chairman and Dr. Taylor is Professor and Chairman, Department of Psychiatry and Behavioral Sciences, University of Health Sciences/the Chicago Medical School, Building 50, North Chicago, Ill. 60064.

psychiatric unit of a metropolitan teaching hospital (12).

In this study we have modified our original inclusion criteria for mania by adding the required flight-of-ideas or grandiosity. Required criteria include 1) hyperactivity, 2) rapid or pressured speech, 3) euphoric, expansive, or irritable mood, 4) flight-of-ideas or grandiosity, and 5) no evidence of psychostimulant drug abuse or medical illness known to produce psychiatric symptoms.

We then identified within this group all patients who also experienced one or more of the following first-rank symptoms (FRS): 1) audible thoughts (thought broadcasting), 2) voices conversing about the patient or commenting on his thoughts or behavior (complete auditory hallucinations), 3) experiences of influence, 4) experiences of alienation, and 5) delusional perception.

We define this subgroup as "schizo-affective disorder, manic type," and the remainder of the group as "manic disorder." These criteria are somewhat narrower than those of the *RDC*, but all patients in both groups satisfy the corresponding *RDC* criteria.

We then compared the two groups for clinical psychopathology, individual history, demographic variables, family history of psychiatric disorder, and response to treatment, using a previously described method (12).

RESULTS

Of the 88 patients who satisfied the study criteria, 78 were diagnosed as manic and 10 as schizo-affective. The mean ages were 40.4 years for the manic group and 38.0 years for the schizo-affective group (n.s.), and their mean ages at onset of illness were 27.8 and 30.5 years, respectively (n.s.). Manic patients had an average of .82 episodes of illness per ill patient year, compared with .94 episodes for schizo-affective patients (n.s.). In the manic group, there were 45 women and 35 men, and in the schizo-affective group, there were 4 women and 6 men (n.s.).

The treatment response (4=full remission), rated by a "blind" investigator, was quite favorable for both groups, with a slight but statistically insignificant advantage for the schizo-affective group (3.50 versus 3.15). The data in table 1 show no differences between the groups for a variety of clinical psychopathological variables, including the presence of two or more good prognostic signs (e.g., sudden onset, precipitating event, broad affect, good premorbid adjustment, and clouded consciousness). Table 2 shows no differences between the groups for current treatments, individual history of associated psychiatric morbidity, or family history of psychiatric illness.

Although it is possible that the small sample size for the schizo-affective group contributed to our failure to differentiate the groups significantly on any variable, for the most part there is a marked similarity between groups for the percentage of patients exhibiting a particular variable.

TABLE 1
Clinical Psychopathological Variables for the Diagnostic Groups

Variable	Manic Group (N=78)		Schizo-affective Group (N=10)	
	Number	Percent	Number	Percent
Good prognostic signs	70	90	9	90
Hyperactivity	78	100	10	100
Rapid/pressured speech	78	100	10	100
Euphoric	34	44	6	60
Expansive	48	62	6	60
Irritable	59	76	8	80
Labile	46	59	3	30
Flight-of-ideas	32	41	4	40
Grandiosity	55	71	7	70
Persecutory delusions	43	55	6	60
Nudity	26	33	3	30
Fecal incontinence/ smearing	11	14	1	10
Head decoration	29	38	3	30
Violence	36	46	4	40
Confusion	20	26	1	10
Auditory hallucinations	34	44	5	50
Other hallucinations	20	26	3	30

TABLE 2
Treatment, Individual History, and Family History for the Diagnostic Groups

Item	Manic Group (N=78)		Schizo-affective Group (N=10)	
	Number	Percent	Number	Percent
Treatments received*				
Neuroleptics alone	11	16	4	40
Lithium ion	34	49	3	30
Neuroleptics plus lithium ion	13	19	0	0
ECT (alone or combined with medication)	10	14	3	30
None	1	1	0	0
Individual history				
Alcoholism	33	42	3	30
Sociopathy	8	10	1	10
Drug abuse	16	21	4	40
Family history for first-degree relatives**				
Ever ill with affective disorder	51	14	5	14
Ever ill with alcoholism	39	11	4	11
Ever ill with schizophrenia	0	0	0	0

*Adequate data available for 69 manic patients.
**Adequate data available for 67 manic patients (355 first-degree relatives) and 7 schizo-affective patients (36 first-degree relatives).

The *RDC* (as well as the working draft of *DSM-III*) employs duration of illness as one classification axis, and we considered the possibility that our two groups might have differed on this variable. The mean duration of illness for the index episode was somewhat longer for the schizo-affective (15.12 weeks) than for the manic group (10.79 weeks), but this difference was not statistically significant (t=.66)

DISCUSSION

There are no generally accepted specific criteria for schizo-affective disorder, manic type, and no two studies have used exactly the same criteria. We chose FRS to separate schizo-affective disorder from manic disorder as these abnormal experiences can be rated reliably, are considered by many to be diagnostic for schizophrenia, and figure prominently in the *RDC* for schizo-affective disorder.

Some investigators would certainly broaden the schizo-affective group by adding one or another phenomenological criterion. Few would disagree, however, that patients with a prominent affective syndrome plus FRS ought to be prime examples of any schizo-affective grouping.

Using these straightforward criteria, we are unable to differentiate mania from schizo-affective disorder, manic type, using a group of variables that we believe are critical in the validation of psychiatric disorders. We present these data in the hope that others will be prompted to do similar analyses, eventually providing a data base adequate to assess the validity of the diagnosis of schizo-affective disorder.

Coffee Consumption Among Psychiatric Inpatients

BY DANIEL K. WINSTEAD, M.D.

Of 135 patients on an acute psychiatric ward, 34 were "high users" of coffee. The high users tended to be older, single, and have diagnoses of psychosis. They showed significantly more state anxiety than other patients, but there were no differences in trait anxiety or MMPI scores. Further research is suggested to determine whether high caffeine consumption among inpatients may be related to staff coffee-drinking behavior and/or treatment with anticholinergic drugs.

CAFFEINE is the most widely used central nervous system stimulant. In 1972, Americans spent more than $1.2 billion for 2.8 billion pounds of coffee—more than

When this work was done, Dr. Winstead was Major, MC, U.S. Army Hospital, Nuremberg, West Germany. He is now Chief, Psychiatry Service, Veterans Administration Hospital, 1601 Perdido Street, New Orleans, La. 70146.

The author wishes to acknowledge the assistance of Ms. Sharon Barber, Mr. Harry Megaw, and the nursing staff of Ward 4-Main of the U.S. Army Hospital, Nuremberg, West Germany.

150 billion cups of coffee. This represents a per capita consumption of 14.3 pounds (1). Although heavy use of caffeine produces dependence, tolerance, and withdrawal symptoms (2), the general public has been reluctant to classify caffeine as a drug. This reflects the drug's "domestication," i.e., its incorporation into our daily life in such rituals as the coffee break and the coffee club (3).

In a recent article, Greden (4) reported the multiple side effects of excess caffeine ingestion and commented on the frequent misdiagnosis of anxiety neurosis in cases of caffeinism. The symptoms of irritability, nervousness, palpitations, restlessness, disturbed sleep, gastrointestinal irritation, and diarrhea are common to both disorders, and only a careful dietary history distinguishes the two. To complicate matters further, the symptoms of caffeine withdrawal can also mimic those of an anxiety state, with nervousness, restlessness, and headache being the most common complaints (5–7). Although Greden noted "chronic coffee drinking [of] patients on inpatient psychiatric services," he gave no supporting data. He suggested further investigations of the prevalence and incidence of caffeinism.

In previous reports (8, 9) I have evaluated drug-seeking behavior among psychiatric inpatients with respect to the use of minor tranquilizers as well as analgesics. These studies revealed a correlation between individual anxiety levels and the extent of use of such drugs when made freely available. During these studies, it became evident that there was another drug freely available to all of these patients on the ward—caffeine, in the form of coffee. Many patients drank excessive amounts of coffee, but those with a diagnosis of alcoholism seemed to be particular offenders. Many patients purchased large beer mugs which they continually refilled with coffee.

The present study was undertaken in an attempt to quantify coffee consumption in an inpatient psychiatric setting and thus to identify the high user of caffeine. The hypothesis was that high coffee consumption would be closely correlated with both high levels of anxiety and diagnoses of alcoholism.

METHOD

The study was conducted on the 27-bed psychiatric unit of the U.S. Army Hospital in Nuremberg, Germany. Although this facility also treats dependents, most patients are active duty military personnel. Eight to 10 of the beds are generally occupied by patients in a 4-week alcohol rehabilitation program. The remainder of the ward is an acute treatment facility; chronic patients are generally evacuated to a larger Army hospital in the states. The patient/staff ratio is approximately 1:1, with a 5:1 ratio for each of the shifts. Five psychiatrists share the responsibility for these patients.

All patients admitted to the unit were initially included in the study. During their first 5–7 days of hospitalization, they were given the State-Trait Anxiety Inventory (10), the Minnesota Multiphasic Personality Inventory (MMPI), and a questionnaire that examined their prior use of coffee, tea, and other drugs. Coffee was freely available on the ward between the hours of 6 a.m. and 10 p.m. On an average day, 15 gallons of coffee were consumed by patients and staff. All patients were instructed to record each cup of coffee that they drank throughout the day, and these records were collected daily and reviewed by the staff. Patients were subsequently interviewed in an attempt to determine the accuracy of their daily records.

RESULTS

During the 3-month period, a total of 188 patients were admitted for varying intervals. The data are based on the 135 patients for whom psychological testing could be completed before discharge. The majority of patients not included were hospitalized 4 days or less.

Thirty-four of the 135 patients tested (25%) were identified as "high users" of coffee, defined as drinking 5 or more cups of coffee on 2 or more days during their hospitalization. This cut-off point of 5 cups represents a minimum of 500 mg of caffeine, a large dose (4, 5). Table 1 presents demographic data for high users compared to the other patients in our sample. The high users were older and more often single, divorced, or separated. In addition, they had a higher incidence of psychosis and a lower incidence of depressive neurosis. Therefore their hospital stays were longer and they were more likely to be evacuated to a stateside hospital than the other subjects. Given the higher incidence of psychosis in the high-user group, it is not surprising that they were treated with phenothiazines or antidepressants more often than the other patients. Patients in the high-user group had a significantly higher level of state (current) anxiety than the other group (mean scores=51.7 and 49.6, respectively, $p \leqq .05$). Scores on the trait (personality) anxiety scale were almost equal. It is of particular interest that none of the high users was given a diagnosis of anxiety neurosis. Interestingly, the coffee consumers revealed less psychopathology on 9 of the 13 MMPI scales, although there were no statistically significant differences between the groups.

The results of the questionnaire survey are presented in table 2. The high-user group reported an average daily intake of 6.7 cups of coffee compared with 3.2 cups in the other group. Both groups reported a rather high incidence of nervousness from overindulgence in coffee, and a substantial percentage also reported physical symptoms when they drank less coffee than usual. There were, however, significantly more reports of anxiety symptoms on withdrawal from caffeine in the high-user group.

Patients in the two groups reported similar patterns

TABLE 1
Demographic Data for High Users of Caffeine and Other Patients

Item	Group: High Users (N=34)	Group: Other Patients (N=101)	Significance*
Mean age (years)	29.2	25.6	p≤.05
Male (percent)	91	83	p≤.05
Living with spouse (percent)	21	44	p≤.05
Mean hospital stay (days)	20.9	14.2	p≤.05

Evacuated to U.S. hospital (percent)	41	16	p≤.05

*By point-biserial analysis (age and length of stay) or significant difference of proportions.

TABLE 2
Results of Questionnaire on Caffeine Consumption Among Psychiatric Inpatients

Item	Group: High Users (N=34)	Group: Other Patients (N=101)
Daily consumption		
Coffee (cups)	6.7*	3.2
Tea (cups)	0.3	0.7
Colas (number)	1.3	2.5
Self-reports of caffeine effects (percent)		
Deny dependence	24	19
Side effects from excessive intake	17	17
Anxiety symptoms from consumption	30	24
Physical withdrawal symptoms	10	7
Anxiety withdrawal symptoms	26**	5

*Significantly different (p≤.05, point-biserial analysis).
**Significantly different (p≤.05, significant difference of proportions).

of use of analgesic medications. Since this study was done concurrently with a study designed to quantify the use of available-on-demand analgesics (9), additional data concerning the use of these drugs were available. Only 28% of the high-user group availed themselves of analgesic medication (propoxphene napsylate) compared with 40% of the other patients (p≤.05, significant difference of proportions). Furthermore, only 3% of the caffeine group compared with 16% of all other patients used these medications frequently (p≤.05, significant difference of proportions). Thus, the coffee consumers were actually less likely than the other patients to use or abuse analgesics under the hospital conditions.

Two cases of caffeinism were identified. The first, a 22-year-old man, had been admitted with a diagnosis of schizophrenia. On his eighth day of hospitalization he complained of palpitations, restlessness, increasing anxiety, and anorexia. An EKG revealed paroxysmal atrial tachycardia. When questioned about his coffee consumption, he reported that he had been drinking 10–15 cups of coffee a day. He was counseled in this regard and immediately stopped drinking coffee. His tachycardia disappeared within 48 hours and he reported a lessening of his anxiety. The second patient was a 29-year-old man who was transferred to the psychiatric ward from the surgical service, where he had recently undergone a vagotomy and pyloroplasty for bleeding duodenal ulcer. Before his transfer for further treatment of an agitated depression, he had been placed on a bland diet and instructed to avoid caffeine entirely. In spite of the warnings, he drank 7–12 cups of coffee during each of his first 2 days on the psychiatric service. He developed anxiety of panic proportions and had increased abdominal pain. Following further counseling, he voluntarily reduced his coffee intake to 2 cups a day and his abdominal pain and anxiety abated within 24 hours.

DISCUSSION

The results of this study indicate that the high user of coffee on a psychiatric inpatient service tends to be an older man who is unmarried or not living with his spouse. Although alcoholism was the most prevalent diagnosis, the proportion was not different from that of the ward in general. However, there were significantly more psychotic patients in the high-user group, who tended to be hospitalized longer and were more frequently evacuated to a stateside hospital.

The anxiety inventory revealed a statistically significant elevation in state anxiety for the high-user group. It is unclear whether this high anxiety level is the direct result of caffeine intoxication or whether it motivates chronic coffee drinking. Further research would be necessary to answer this question definitively, but I suspect that both factors are operative. Since the high users were less often users or abusers of analgesics, their drug-seeking behavior on the ward was not generalized; rather, it was specific for caffeine in the form of coffee.

The results of this study are comparable to the questionnaire data reported by Goldstein and Kaizer (5). In a survey of 239 housewives, they found a 26% rate of heavy caffeine use (again defined as more than 5 cups of coffee a day), which is approximately the same incidence found in the inpatient population I have studied. The heavy users in both studies reported more symptoms of caffeine withdrawal, such as nervousness, irritability, and restlessness. Goldstein and Kaizer also found that the heavy users were older; they speculated that the coffee habit may take several years to develop.

The finding of a higher proportion of psychotic

patients in the high-user group was of particular interest. Increased water ingestion has long been considered a reliable physiologic measure distinguishing schizophrenics from normal controls (11, 12). In a recent report, Raskind and associates (13) described a syndrome in postmenopausal women of "agitated psychotic depression, increased water ingestion, and electrolyte values consistent with the syndrome of inappropriate antidiuretic hormone secretion." Although none of our patients was diagnosed as having water intoxication, the possibility that underlying brain physiology might explain their coffee drinking behavior should not be discounted. A much more likely explanation, however, would be that many of these patients were suffering from the dry-mouth side effect that so frequently results from the potent anticholinergic action of the phenothiazines and tricyclic antidepressants. As mentioned earlier, 38% of the high users were taking these medications during their hospitalization compared with only 28% of all other patients. All of the psychotic patients in the high-user group were on these medications during hospitalization.

Coffee is a poor choice of beverage for the schizophrenic or psychotic patient. Caffeine would be expected to increase the patient's anxiety level; further, a case of caffeine intoxication that resulted in psychotic decompensation has been reported (14). In addition, caffeine is known to interfere with bedtime sedatives (15) and may also interfere with other psychopharmacologic agents (4). One wonders whether the psychotic patients were not trying to counteract the unpleasant sedative effects of their medication by drinking coffee.

There are some obvious methodological problems in this present study. First, we were dependent on patients' memory and honesty. Second, no attempt was made to measure consumption of any other beverages containing xanthines or of those beverages consumed off the ward by patients with hospital privileges. Had we been able to gather these other data, we might have found a much greater percentage of high users. A more controlled environment and the use of a token system would give a more accurate picture of actual consumption patterns. In addition, staff patterns of coffee consumption should be evaluated. Clinical observations during this study suggested that many of the psychiatric staff were as guilty as the patients of excessive caffeine ingestion, and some of the patients may have been modeling this staff behavior.

The Psychotherapist and Informed Consent

BY JOHN O. NOLL, PH.D.

The author points out that psychotherapists are being increasingly required by law to function as instruments of social control. He believes it is incumbent on therapists to employ full and informed consent procedures with their patients in regard to the effects of providing psychiatric information to potential employers, insurance carriers, and other third parties.

ONE OF THE WAYS in which psychotherapists may exercise power over others is by assuming the role of double agent (1). Whenever the mental health professional is employed by an agency or by an institution, the institution's needs will almost invariably supersede those of the patient. Bazelon (2) referred to a basic, usually unacknowledged antagonistic relationship between the individual and the hospital or institutional professional. He also gave illustrations of the influence that the professional's own hidden agendas have in determining the professional's conduct toward the patient, e.g., such concerns as public relations.

Halleck (3) stated,

> A patient . . . usually assumes that the doctor has no other purpose except to help him; he may not know or may easily forget that his psychiatrist also holds allegiance to an agency. Therefore, the patient may reveal things that can lead the psychiatrist to make decisions that result in denying the patient privileges. (p. 120)

In other words, the individual incriminates himself.

The double agent functions of psychiatry represent what Szasz (4) referred to as institutional psychiatry, contrasted to what he called contractual psychiatry (p. xxiii). The distinguishing characteristic of the latter is that individuals who independently seek psychotherapeutic help make their own contractual arrangements with a mental health professional in private practice. In a contractual arrangement the therapist is presumed to place the interest of his or her client above any other outside interest. As a consequence, patients need not fear that what they confide to their therapist will be used against them in any way.

With rare exceptions this assumption is undoubtedly correct, but there are circumstances that combine to transform the private contractual relationship into a double agent situation. These particular circumstances have been explored only recently (5, 6). A brief examination of these circumstances will reveal that in several ways individuals who seek contractual psychotherapeutic help from an independent private practitioner are placing themselves in as much jeopardy as those who seek help from institutional therapists.

DOUBLE AGENT SITUATIONS

Over the past several years there has apparently been a vast increase in the number of requests for information from mental health professionals regarding former patients (3, 7). These requests emanate largely from employers who are interested in prospective employees' psychological or psychiatric backgrounds. Employers are including on employment application forms some variant of the following question: Have you ever received treatment for an emotional or mental problem?

Individuals who have received or are receiving psychotherapy or counseling have two alternatives: they may answer yes or no to the question. If they are "honest," they will respond affirmatively; if they feel that this is a private matter, they may answer no. When individuals reply yes to the question they engage in their own incrimination and place their prospects for employment in jeopardy. Once they have indicated an affirmative response they are typically requested to sign a waiver form that permits the employer or his or her representative to communicate with the applicant's former or present therapist. If the applicant wants the job, he or she has no choice but to give consent to allow the employer to obtain highly sensitive personal information that may be used repressively; i.e., the employer may not hire the applicant because of the information obtained from the individual's therapist.

When individuals grant their consent by signing the waiver they also risk converting the therapist into a double agent because most therapists will respond to requests for information that are accompanied by a signed waiver. The kind of reply that the therapist formulates will determine how much harm is done to the patient. That a reply to a request for information can be an agonizing process for the therapist is illustrated by some of Halleck's comments regarding such requests (3):

> The psychiatrist who receives a request for information about a former patient . . . is in a difficult moral position.

Dr. Noll is Professor and Director of the Clinical Training Program, Department of Psychology, University of North Dakota, Grand Forks, N.D 58201.

> If the patient was not too disturbed and if the psychiatrist knows that he benefited from treatment, he can write some highly commendatory things about his client and there will be few complications. The psychiatrist's conscience will thus be clear and his patient will get his job or his policy. Usually, however, the situation is more equivocal. The psychiatrist frequently knows that some of the things he might reveal could prevent his former patient from getting a job or a policy. Sometimes there is very little the psychiatrist can say that would be favorable; if he responds honestly, the patient loses. (p. 125)

Although Halleck made this statement as an institutional psychiatrist, his comments reflect the dilemma of most private practitioners who are the recipients of requests for information accompanied by a signed waiver. The therapist who was once the patient's agent becomes a double agent with virtually unencumbered potential for using his or her knowledge about the patient repressively. If the therapist was pleased with the outcome of his or her contacts with the patient, a highly commendatory statement about the patient may overcome the stigma the patient may carry for having sought therapy in the first place. If the therapist was not pleased with the patient, the situation is more equivocal, and the communication written to the employer may be accompanied by a depreciating, stigmatizing label as well as a damaging character reference.

Halleck's statement also mentions another sphere of individual autonomy that may be jeopardized as a consequence of having seen a therapist, the application for insurance, particularly life insurance. Insurance applications almost invariably include a question regarding the status of the person's mental health. Again, should the person respond affirmatively to the question he or she will be required to sign a waiver form that allows the insurance company to request information from the therapist. As in the instance of the employer's request, the therapist is forced into a double agent role. The information and diagnosis that the therapist provides will contribute to the insurance company's decision to either grant the policy at the usual actuarial rates, grant the policy but with higher premiums, or reject the application.

One of the inherent dangers for individuals who are refused an insurance policy resides in the probability that the damaging information is likely to be put into a central computer system such as the Medical Insurance Bureau in Boston, Mass. A central computer system can make potentially repressive information available to any other insurance company. Such information is becoming more available because increasing numbers of health insurance policies have been including coverage for mental health care.

INFORMED CONSENT

It would appear that psychotherapists may find it necessary to take the concept of informed consent more seriously (8). In medicine, full and informed consent demands that physicians inform their patients fully of their condition and what procedures or treatment will be required to help their condition. In addition, patients are to be informed of the risks involved as a result of the treatment. Patients may then give their consent to the treatment or may decide not to undergo treatment because in their view some of the consequences of the treatment are unacceptable. If we analogize to the psychotherapeutic relationship, it would seem that it is incumbent on the therapist to inform prospective patients of the risks they may take with reference to future employment possibilities or future insurability.

A similar problem arises when potential patients wish to exercise their option of seeking psychotherapy under the provisions of a health insurance policy that covers mental health care.[1] If individuals wish to exercise this option it would appear that psychotherapists have an obligation to inform them of the potential hazards that exist with respect to diagnosing their condition initially and providing the insurance carrier with periodic information regarding the nature of their problems at any particular time throughout the course of therapy. It is possible that many patients may not be immediately concerned about the information that is sent to insurance carriers about themselves. However, this does not obviate the therapist's need or responsibility to fulfill the obligation called for under the concept of full and informed consent. If nothing else, it does provide the patient with a choice; he or she may even decide to pay out of pocket. If the psychotherapist does not employ informed consent procedures, he or she may act unwittingly as a double agent while the patient who sought him or her out in the first place for help will suffer the consequences of not having been informed.

The above examples are illustrative of the many other circumstances that place the therapist in the role of double agent. Examples of other applications that contain inquiries that may have untoward results for the patient are those for college admission and a driver's license.

LEGAL PRESSURES

There are other newly emerging pressures that might transform the psychotherapist into a double agent through legislative action and judicial decision. In essence, the new laws and judicial decisions appear to be explicitly transforming the psychotherapist into an instrument of social control.

Two examples may be cited to illustrate what may be an emergent and growing trend throughout the

[1] If therapists employed a policy of having no contact with third parties under any circumstances, there would be no particular difficulty with these considerations. However, with the advent of third-party payers most therapists will probably prefer to adopt full and informed consent procedures.

country. During the past several years many states have enacted child abuse and child neglect legislation. Typically, such laws include the mandatory reporting by various professionals and others of suspected instances of child neglect or abuse. One such recently enacted law (9) states,

> Any physician, nurse, dentist, optometrist, medical examiner or coroner, or any other medical or *mental health professional*, school teacher or administrator, school counselor, social worker, day care center or any other child care worker, police or law enforcement officer having knowledge of or reasonable cause to suspect that a child coming before him in his official or professional capacity is abused or neglected shall report the circumstances to the division. (italics added)

The recent *Tarasoff* decision by the Supreme Court of California (10) provides another example of the trend toward making psychotherapists instruments of social control. In this case the court held that if a patient expresses a death threat toward a third party it is the responsibility of the psychotherapist to inform that third party or that third party's responsible relatives of the nature of the threat.

If other states adopt this ruling, and if other legislative action is undertaken to provide for the reporting of other types of behaviors that society would like to control, the following implications for the practice of psychotherapy are immediately apparent: 1) greater numbers of patients will incriminate themselves and be subject to legal action, 2) psychotherapists may well have to defend themselves in courts of law for making allegations about patients, 3) a basically antagonistic relationship may develop between the patient and the psychotherapist, 4) therapists acting in accordance with the principle of full and informed consent may well deter patients from seeking their help, and 5) ultimately, fewer and fewer people will avail themselves of psychotherapeutic services because of the fear that they may talk about the "wrong" things or express unacceptable feelings or desires.

In his discussion of privileged communications, Slovenko (11) said,

> The privilege's exceptions, for all practical purposes, render the privilege a nullity. As a shield, it provides very little protection. Aside from no record keeping, one solution is that the psychiatrist also be a priest, for then he could, like a character in William P. Blatty's book, *The Exorcist*, say, "I can always tell the judge it was a matter of confession." (p. 70)

One implication of this for therapists who reject functioning as agents of social control would be to incorporate as a religious body, thereby placing their services under constitutional protection.

COMMENT

In view of several of the above considerations, it would seem that the professional organizations to which most psychotherapists and counselors belong might address themselves to the basic autonomy of the function of the psychotherapist. If this is not done, if the basic functions of the psychotherapist are not protected, psychotherapists will, in fact, become more and more instruments of social control.

Catatonialike Symptomatology and Withdrawal Dyskinesias

BY MICHAEL I. GOOD, M.D.

The author describes a patient who presented catatonialike symptoms and dyskinesias associated with glutethimide discontinuance and antihistamine use. He hypothesizes that altered dopamine metabolism may produce some of the unusual neuropsychiatric characteristics of glutethimide withdrawal. Drug-withdrawal catatonia may be an additional entity in the differential diagnosis of catatonialike states of organic etiology.

DESCRIPTIONS OF drug-withdrawal states exhibiting signs and symptoms referable to the basal ganglia have appeared with increasing frequency in recent years (1–6). This report presents an unusual case of glutethimide (Doriden) discontinuance associated with antihistamine use in which a catatonialike state with oral-facial dyskinesia complicated the early diagnostic picture. The case illustrates the possible organic etiology of catatonia and catatonialike states (7–9). I will also discuss the glutethimide withdrawal syndrome, withdrawal dyskinesias, catatonia of organic etiology, and possibly related biochemical factors.

CASE REPORT

A 37-year-old divorced woman teacher with confusion and facial twitching was transferred to an emergency ward from another hospital after unsuccessful treatment with 50 mg of intravenous diphenhydramine (Benadryl) for a presumed drug-induced dystonic reaction.

The patient had experienced a series of stressful events in the 18 months before her admission. The family home was burglarized, her adolescent daughter became pregnant and left home, the patient was assaulted, and she reportedly developed mononucleosis. Brooding and depressed, she had stopped working 5 months previously when her job lost its funding. She had no history of psychiatric or neurological problems.

One week prior to admission, the patient reportedly developed headache, bronchial cough, and coryza. Three days later she experienced nausea, for which she took 50 mg of cyclizine (Marezine), using the 12 available tablets over a period of several days. She had also used glutethimide (reportedly never exceeding 0.5–1.0 g nightly) for sleep for 2–3 years and had recently exhausted her supply. The morning of her hospital admission, family members noted that she had incoherent speech. They also found the now empty glutethimide and cyclizine containers.

On admission, she was alert and frightened-looking, with tear-filled eyes, marked facial grimacing, and hand tremors. She maintained a recumbent posture. Initially she was suspicious and negativistic toward extended neurological examination. She spoke softly and incoherently or was mute, but she obeyed simple commands. Her first audible words were, "I am being born." Waxy flexibility of her arms was demonstrable. Psychiatric consultation was requested for possible commitment in view of the apparently catatonic nature of her psychosis, her history of depressed mood, the evidence of psychiatric precipitants, and possible drug ingestion.

Subsequently, however, she manifested extensor plantar reflexes and impairment of orientation, recent memory, and intellectual functioning. There were no other positive findings on general physical and neurological examination. A general serum toxic screen (including testing for glutethimide and antihistamines) was negative, and no other evidence of acute ingestion was found. Lumbar puncture, skull films, echo brain scan, chest and abdominal X-rays, and extensive serum and cerebrospinal fluid laboratory testing yielded no findings that accounted for her symptoms.

Twelve hours after admission she hallucinated a human figure and developed a generalized convulsion, which did not recur after treatment with diphenylhydantoin. An EEG showed generalized 6–7 Hz activity and bursts of 5–6 Hz high-voltage activity; a similar pattern appeared 24 hours later. The EEG pattern was consistent with a withdrawal or subclinical seizure state. A second lumbar puncture and toxic screen were negative. Over the next 4 days her confusion and grimacing abated and she was able to return to her home. She continued to do well and was diagnosed as having had an adverse drug reaction. At follow-up 1 year later, she had remained off sleeping medication, obtained employment, and experienced no recurrent symptoms.

DISCUSSION

Glutethimide

How is the clinical picture of this patient to be understood? With the exception of the catatonic symptoms, her course is consistent with the glutethimide withdrawal syndrome as it has been described in the literature. Glutethimide addiction was first reported in this country in 1957 (9), and subsequent papers have reviewed experience with chronic and acute glutethimide intoxication, dependence, and withdrawal phenomena (10–14). Reported withdrawal symptoms include headache, tremors, fasciculations, facial grimacing, seizures, myoclonus, anxiety, insomnia,

Dr. Good is Associate in Medicine (Psychiatry), Peter Bent Brigham Hospital, 721 Huntington Ave., Boston, Mass. 02115, and Director of Children's Services, West-Ros-Park Center, West Roxbury, Mass.

nightmares, hyperactivity, disorientation, confusion, delirium, hallucinations, paranoid delusions, sweating, fever, chills, piloerection, nausea, abdominal cramps, and tachycardia. The EEG in the withdrawal state may show generalized theta activity of medium voltage, intermixed with runs of irregular, high-voltage delta activity (15). Curiously, regular and moderate doses of glutethimide (0.5–3.0 g daily) have been reported to produce symptoms resembling the withdrawal syndrome, even when there is no history of discontinuance (12). Acute intoxication without prior history of excessive use also can apparently cause withdrawal-type symptoms (11, 13), although chronic or excessive usage may have preceded the acute symptomatology in these unusual cases (15). Factors that may predispose an individual to withdrawal phenomena include irregular absorption, rapid and unusual metabolism (13), the accumulation of a potent, active metabolite (16), and intercurrent illness.

Dopaminergic-Cholinergic Balance Hypothesis

The patient's catatonialike symptoms warrant explanation in terms of medication-withdrawal effects in view of the acute, drug-related nature of the psychosis and the absence of other findings consistent with a diagnosis of schizophrenia, major affective disorder, intoxication, or organic disease. To support such an explanation, it is necessary to consider two points. First, glutethimide has pronounced anticholinergic properties that can cause excitatory effects, including seizures (13), as well as depressant effects. These properties may account for the antiparkinsonian effects of the drug (17). Second, a balance between dopaminergic and cholinergic influences has been proposed for normal functioning of brain striatum (18). Thus, the withdrawal of glutethimide could alter the dopaminergic-cholinergic balance by either cholinergic rebound or dopamine-mediated effects on nigrostriatal pathways (19). Such alteration might account for the appearance of certain neuromotor signs characteristic of glutethimide withdrawal, such as facial grimacing and myoclonus.

Of further interest is the observation that some antihistamines inhibit dopamine reuptake by striatal neurons, and this rather than their anticholinergic effect may be the reason for their beneficial effect in parkinsonism (20). Prolonged use of antihistamines has recently been reported in association with oral-facial (tardive) dyskinesias (4), the mechanism of which has been theorized to be alteration of central dopaminergic pathways by blocking reuptake of dopamine by individual neurons (5). Moreover, the caudate nucleus appears to be involved in the production of experimental catatonia, and dopamine receptor blockade has been proposed as the mechanism of action of neuroleptics that produce catatonia in animals and a parkinsonian syndrome in man (19).

These observations are especially pertinent to this case report, since it is likely that additive or interactive effects of the glutethimide and antihistamines led to significant alteration in the metabolism of dopamine and reduction in its intracellular concentration. The catatonialike phenomena may thus be related to prior inhibition of dopamine reuptake by striatal neurons with subsequent receptor hypersensitivity or hyperstimulation, analogous to the mechanism proposed in the production of experimental catatonia. Such a neurochemical withdrawal state would be more likely if long-term use of glutethimide contributed to altered dopamine metabolism than if the antihistamines alone did so, especially since the antihistamines were used relatively briefly in this case.

Withdrawal Dyskinesias

It is worthwhile to compare glutethimide withdrawal reactions with those caused by other drugs. Facial grimacing is reported in association with abrupt discontinuance of butyrophenones, and one patient developed severe choreiform movements of the arms and legs along with facial grimacing (2). The relatively mild and reversible oral-facial dyskinesias appear to be more analogous to an acute "withdrawal" dyskinesia than to a tardive dyskinesia (2). Other neuroleptic withdrawal symptoms have also been described, and an akathisialike syndrome reportedly can occur with imipramine withdrawal—possibly due to depletion of or hypersensitivity to dopamine in the central nervous system (3). Another paper (6) described a case of athetoidlike flexor-extensor movements of the arms and legs occurring with confusion and disorientation in a 47-year-old woman when she successively received hypnotics and phenothiazines for insomnia associated with pentazocine withdrawal. Interestingly, it was noted that pentazocine causes a decrease in brain dopamine in animals; hypotheses proposed for the movement disorder included a dyskinetic reaction or chronic central structural or chemical changes predisposing to these movements when the other drugs were introduced, as in tardive dyskinesias due to biogenic amine receptor hypoactivity (6). Additionally, myoclonus and choreoathetosis seen in cases of tricyclic antidepressant poisoning and reversed by physostigmine (21) support an amine imbalance hypothesis for these movement symptoms.

I have not found any previous reports of drug withdrawal producing catatonialike symptoms. However, catatonia has been reported in association with sustained large doses of L-dopa (22). Catatonic complications also reportedly occur with phenothiazine therapy (23) and should be distinguished from akinesia.

Catatonia

The major components of catatonia are catalepsy (waxy flexibility), negativism, mutism, incoherence, confusion, stupor, and episodic hyperactivity or excitement (24). Nonschizophrenic catatonic states have been described in association with general paresis, epidemic encephalitis, alcoholism, hysteria, hypnosis, diabetes, narcolepsy, epilepsy, mentally defective chil-

dren, psychoses due to "illuminating gas" and aspirin intoxication (7), brain stem infarction, mesencephalitis, arteriovenous malformation, tumors of the thalamus and pineal body, basal ganglia destruction, frontal lobe tumors, hydrocephalus, subdural hematoma, postimmunization encephalopathy, subarachnoid hemorrhage, and the syndrome of akinetic mutism (9). Cortical and subcortical factors appear to be important in the production of catatonia, and an association between catatonia and impaired physiologic function of the anterior limbic region of the cerebral cortex has been proposed (24). While catatonia of organic origin is more commonly seen with lesions of the frontal lobe, there may be other localizations, extending from the brain stem to cerebral hemispheres (8, 9). Usually lesions fall into one of four anatomical areas: brain stem, basal ganglia, ascending reticular formation, or frontal lobes and limbic system (9). A dramatic and lethal form of catatonia resembling catatonic schizophrenia (fatal catatonia or Stauder's catatonia) may be due to viral encephalitis (25). The possibility of activating a catatonic psychosis with amphetaminelike psychostimulants in otherwise nonpsychotic subjects is rare, although high doses may produce a paranoid psychosis, the mechanism of which may lie in effects on central dopamine (26).

A recent review (27) of differential elements in the examination of patients in a catatoniclike stupor summarized the findings of Joyston-Bechal (28) in 100 cases of stupor, stressing the role of the psychiatrist in mental status testing and emphasizing the fact that every catatonic patient requires a diagnosis.

CONCLUSIONS

Facial grimacing and a catatonialike psychosis may falsely suggest the diagnosis of schizophrenia associated with an antipsychotic-drug-induced dyskinetic reaction. Medications such as antihistamines for treating dystonic reactions, however, might exacerbate what is actually a withdrawal syndrome, possibly due to mutual effects on dopaminergic pathways. The association of a catatonialike state with the withdrawal of glutethimide and the use of antihistamines is compatible with the apparent role of striatal or ascending reticular formation elements in catatonia. Usually features of the glutethimide withdrawal syndrome will alert the physician to the correct diagnosis. The syndrome may occur unexpectedly, however, and caution in the use of glutethimide is recommended.

Patients' Expectations of Therapeutic Improvement and Their Outcomes

BY SIDNEY BLOCH, M.B., PH.D., GARY BOND, PH.D., BRANDON QUALLS, M.D., IRVIN YALOM, M.D., AND ERIK ZIMMERMAN, M.D.

The authors studied the relationship between patients' expectations of therapeutic improvement and their actual outcomes after 8 and 12 months of group psychotherapy. Using patients' self-evaluations and assessments by therapists and independent judges, they found a positive relationship between expectations and outcomes only when assessments were derived from patients. The authors discuss the possibility of a continuing expectational set in patients toward psychotherapy.

THE ASSERTION by Fiske and associates (1) that in psychotherapy "expectancies are always present in both therapist and patient" is indisputable. Their companion statement, however, that "positive expectancies seem to be a necessary condition for therapeutic effectiveness" is enveloped with uncertainty and controversy. In two excellent reviews (2, 3) Wilkins contended that the evidence for the strong influence of patients' expectations of therapeutic improvement on their actual outcomes is slender and that the significance of patients' expectations in determining outcome is more a popular belief than an established finding of research.

A review of the studies on the issue lends considerable to support Wilkins' argument. The data emerging from both approaches to the question—the correlational approach, in which the relationship between measures of patients' expectations and their therapeutic outcomes are examined, and the experimental approach, in which procedures are introduced to modify patients' expectations, either increasing or decreasing them, and examining respective outcomes—are conflicting, sometimes even contradictory. The studies adopting a correlational approach (4–11) have found either a positive linear (4–7), a curvilinear (8), or no relation (9–11) between expectation and outcome variables.

Dr. Bloch is Clinical Lecturer, Department of Psychiatry, the Warneford Hospital, University of Oxford, Oxford 0X3 7JX England. Dr. Bond is Research Fellow, Department of Behavioral Sciences, University of Chicago, Chicago, Ill. Dr. Qualls is Assistant Professor, Department of Psychiatry, Brown University, Providence, R.I. Dr. Yalom is Professor, Department of Psychiatry, Stanford University School of Medicine, Stanford, Calif. Dr. Zimmerman is a resident in the Department of Psychiatry, Yale University School of Medicine, New Haven, Conn.

The purpose of this paper is to report the results of research applying the correlational model in which efforts were made to overcome several of the obstacles that haunt almost all previous studies. The most critical obstacle has been the method of assessing therapeutic outcome. All of the studies cited, except one in which therapists' assessments were used (10), used some form of patient self-report alone. None used a source of assessment wholly independent of the therapy provided. Thus only one study has recognized the importance of relating the expectations of patients to a measure of outcome derived from a source other than the patients themselves. It is generally agreed that patient self-report is too vulnerable to the bias of the patients, who frequently have a need to please the therapist, to satisfy their own predictions and anticipations, or to justify their investment of time, energy, and money in the therapy. Therapist-based assessment is similarly vulnerable to a bias to see improvement.

The expectation variable has been measured in several differing ways, which undoubtedly has contributed to the conflicting research findings. Commonly, the difference between patients' present and expected self-ratings on a symptom checklist has served as an indicator of expectations. By contrast, Brady and associates (10) relied on patients' replies to two projective tests, and Uhlenhuth and Duncan (7) obtained a measure of patients' general optimism about probable outcome of therapy on a simple 7-point scale.

The clinical populations selected and the quality of psychotherapy given to patients have also varied considerably. The patients studied have ranged from psychotic inpatients (10, 11) to outpatients with neuroses and personality disorders. Several of the outpatient-based studies have not described at all the nature of the patient sample, thus precluding any comparisons between research reports. Only in a minority of studies has a substantial period of psychotherapy been provided to the patient. The range has extended from a single interview session to therapy lasting 6 months, but most therapies have not exceeded more than a few weeks. Further, the therapists used have varied from medical students to experienced clinicians, making comparability on this dimension impossible.

Our objective in this project was to test the relationship between patients' expectations and their therapeutic outcomes by paying particular attention to the measurement of these two variables, to the duration

and quality of psychotherapy offered, and to the selection of the sample. Our plan was to measure expectations in as specific a manner as possible, to measure outcomes by an independent source in addition to patient and therapist sources, and to study a clinical sample with neurotic and/or characterological problems who were undergoing conventional long-term outpatient psychotherapy.

METHOD

Clinical Sample

The therapists of six long-term psychotherapy groups in the Stanford University Department of Psychiatry were asked to refer all consecutive newly accepted patients to the study before their initial therapy meeting. Data on 36 patients were collected over a 6-month period in this way. All 36 patients consented to participate in a project designed to "study their progress in group therapy."

Of the 36 patients, 27 were followed for an 8-month period and 21 for 1 year. Nine patients dropped out of the study early by terminating therapy, most within the first weeks. The attrition between 8 and 12 months was due to 3 patients who terminated therapy because they considered themselves to have achieved their goals and 3 patients who terminated because they had given up. Of the 27 patients studied over the 8-month period, 16 were men and 11 were women. Their ages ranged from 21 to 55, with a mean of 33.6. They were all outpatients who were attending group therapy weekly and who had a neurotic and/or characterological disorder. Fourteen patients had a drinking problem as a prominent component of their disorder and were members of groups especially created for patients with drinking problems. It is important to note that problem drinking was only one facet of the clinical presentation of these 14 patients. In most respects they were clinically similar to the other patients in the sample. The groups functioned along the lines of a conventional group for neurotic-type patients except for an additional focus on alcohol (12, 13).

Measures

Patients were clinically interviewed by one of two experienced psychiatrists (S.B., B.Q.) before their entry into group therapy. The product of these interviews was a delineation of the problems the patients wished to work on in their therapy. There was an average of 4.6 problems per patient, with a range of 2 to 9. Commonly cited problems were depression, tension, an inability to achieve intimacy, a specific problem in interpersonal relationships (most commonly marital), purposelessness, difficulty in identifying and/or expressing feelings, and low self-esteem.

For each problem, the patient defined the goal that he or she wished to reach by the end of therapy. Usually this was the converse of the problem, e.g., more pleasure from life, a sense of self-worth, resolution of an interpersonal conflict, or intimate relationships with others.

For each listed problem and associated goal, patients rated the extent to which they expected to achieve that goal through work in therapy on a 9-point scale, with defined points ranging from "not at all" to "totally."

After 8 months patients were interviewed again by the same psychiatrist, and the original constellation of problems was reviewed. Patients then rated the degree to which they had achieved each of the original goals on a 9-point scale, with the same defined points as the scale for expectations. No mention was made of the original expectation ratings obtained 8 months earlier. An identical procedure was followed 4 months later. Both the expectation and outcome variables were the average scores of a patient's ratings on all of his or her problems. All interviews were videotaped with the patient's knowledge and consent.

Before therapy was started, the therapists formulated their patients' clinical problems and selected 3 main problems that they intended to tackle in the treatment of each patient. Eight and 12 months later, the therapists rated each patient's level of change on each of these problems on a 9-point scale, with defined points ranging from "worst possible outcome" through "unchanged" to "best possible outcome." The mean ratings of change on the 3 problems at each follow-up time were used as the therapists' two measures of outcome.

Forty-two members of the clinical faculty of the Stanford University Psychiatry Department, all of whom were experienced psychotherapists in clinical practice, volunteered to view the videotaped patient interviews. Teams of three judges were formed according to their availability to observe the two or three videotaped interviews (the number varied according to how long the patient remained in the study) at one sitting. After observing the pretherapy interview, each team through consensus agreed on a list of problems that they would tackle were they treating the patient and the associated goals toward which they would work. The judges subsequently viewed the interviews taped at 8 and 12 months and reached agreement on the rating of change for each of the listed problems on a scale identical to that used by the therapists. Again, the mean ratings of change at each time were used as the two outcome measures for the independent judges.

RESULTS

Spearman rank correlations were computed to examine the relationships between the patients' average expectation scores and their average achievement scores at 8 and 12 months and between their average expectation scores and the measures of outcome of the therapists and independent judges obtained at those times. Table 1 presents the correlations and their levels of significance. It demonstrates the marked rela-

tionship between the patients' expectations and their own assessments of outcome both 8 and 12 months after therapy started. By contrast, the patients' expectations are totally unrelated to outcome when measured by either therapists or independent judges at both times of follow-up. Scattergrams drawn for the latter pairs of variables showed no particular pattern; there was no evidence of a curvilinear relationship between patients' expectations and outcome.

DISCUSSION

Expectations are related to outcome only when the latter is assessed by the patients themselves. This finding is not inconsistent with the result of previous research in which patients' self-reports were the only outcome measure (4–7). The absence of any relationship between patients' expectations and therapist-assessed outcome is a replication of the results of Brady and associates (10). (It should be noted that because their population and methods of measurement were different from those in the present study, direct comparison is not entirely warranted.) Since to our knowledge no other researchers have used either therapists or independent judges as sources of outcome measurement, our comparisons must be limited to the data of Brady and associates.

In his review of the literature (3) Wilkins argued for an independent source of outcome measurement and was critical of investigators who did not include such an objective measure of improvement. In the present study we heeded his advice by incorporating two sources of outcome other than the patients themselves. In the case of both sources we found no evidence for their relationship with patients' expectations.

The question arises as to why there is a positive relationship between expectations and improvement only when the patient is the source of outcome measurement. Memory is unlikely to be a factor. In some previous studies, in which the duration of therapy was only a single session, it may well be that the patients reported the outcome they had predicted for themselves, i.e., they satisfied their predictions by being able to recall what they had originally anticipated. By contrast, in the present study several ratings of expectations were completed by the patients at one time only, they were at no stage reminded of what these ratings were, and the outcome measures were obtained after several months.

What appears more likely is that both the measurement of expectations of improvement and the assessment of actual improvement are derived from a similar source in the patient. Possibly, patients enter therapy with certain expectational sets that determine thereafter how they perceive their progress and ultimate outcomes. No matter what occurs in the therapeutic process or what changes in patients are actually achieved, they maintain a particular, consistent attitude toward their progress in therapy. Thus some patients reporting a successful outcome are perhaps manifesting their continued faith in therapy or their need to please therapists (and researchers as well) or their continuing need to maintain their belief that rescue is still possible. By contrast, some patients reporting a poor outcome for themselves are possibly demonstrating an element of their psychopathology—a basic, pervasive pessimism about change for themselves.

The data from this study are insufficient either to confirm or refute the hypothesis that the measures of patients' expectations of improvement and patients' assessments of improvement originate in some common factor. Further research could explore this possibility by attempting to identify and study closely various expectational sets in patients as well as the criteria by which patients assess themselves on outcome.

In the interim, we are left with the finding that there is no relationship between patients' expectations and two external measures of outcome. This finding supports Wilkins' point that it is indeed more a popular belief than a confirmed research finding that patients' expectations of improvement affect their therapeutic outcomes.

Attitudes of Psychiatric Residents Toward Payment of Psychotherapy Fees

BY BARNETT S. MEYERS, M.D.

A preliminary exploration of psychiatric residents' thinking on the subject of psychotherapy fees revealed a pattern of inconsistencies in attitudes and a divergence between attitudes and practice. The author discusses these findings in the light of theoretical considerations and the effect of such attitudes on clinic administration and patient treatment. He emphasizes education about and discussion of fees as important aspects of residency training.

THE RECOGNITION of the theoretical and clinical significance of the fee for service in dynamic psychotherapy has been a major contribution of psychoanalytic thinking (1). Despite this, there is a singular dearth of material in the literature concerning the study or discussion of the attitudes of psychiatric residents toward their patients' fees, although Pasternack and Treiger (2) addressed this subject in a recent paper, noting the "questionable" fee-setting practices of residents. These authors discussed the educational and administrative procedures that were developed to deal with this situation. The resident's difficulties in dealing with the financial aspect of the therapeutic situation are often manifested by his failure to discuss the subject during supervisory sessions. One frequently discovers that the resident has "forgotten" to record process notes of the session in which the fee was discussed.

Freud's warning that "money matters are treated by civilized people in the same way as sexual matters—with the same inconsistency, prudishness and hypocrisy" (3, p.131) remains relevant here. In consonance with modern society's apparently liberal attitudes toward sexuality, patients, residents, and supervisors now find the discussion of frankly sexual material both more comfortable and appropriate. Underlying transference and countertransference conflicts are more directly manifested in the continued aversion to the subject of money.

This aversion is augmented by the fact that psychiatric residents can easily rationalize that patients' fees have little to do with their own incomes, material sustenance, or "professional concerns" for patients. This "fantasy" is enhanced by the commonly shared first-year inpatient experience in which payment for service is negotiated between the hospital and the third-party payer. The resident enters his/her outpatient years relatively "pure" of monetary contamination. It is strikingly ironic that reimbursement for service does play a major role in the support of all services on which residents receive training. This has become increasingly true with the cutbacks in National Institute of Mental Health funding.

An interesting paradox is that the resident does not have easy access to the "my standard fee" solution used by many private practitioners. (Furthermore, one wonders to what extent this solution serves to protect senior practitioners from dealing with issues that were not resolved during their own training.) Most commonly, the training facility, having a public institutional base, is required to use sliding scale fee schedules for ambulatory patients in addition to accepting Medicaid. The flexibility of the sliding scale and the no-direct-payment aspect of Medicaid would seem to be ideal ve-

At the time this work was done Dr. Meyers was Chief, Department of Psychiatry Outpatient Clinic, Brookdale Hospital Medical Center, Brooklyn, N.Y., and Assistant Clinical Professor of Psychiatry, New York University Medical School, New York, N.Y. hicles through which trainees could be helped to understand their attitudes about their patients' fees as well as the role such fees play in psychotherapy. The present study was designed with this in mind. The hope was that this rather preliminary survey would itself open up monetary attitudes and practices as subjects for discussion.

PROCEDURE

A questionnaire was distributed to 2 different second-year groups totaling 15 residents and 1 group of 5 third-year residents as an "inquiry of residents' feelings about the clinic fee structure and how it might be changed." The questionnaires were completed early in each of 2 successive academic years. Residents were asked to estimate the average fees they were charging their patients. Other questions asked for personal preferences among various mechanisms for fee setting and collection. Data were also collected and studied to compare the residents' responses to the questionnaire with their actual fee-setting and collection practices.

RESULTS

Although the study was not designed to elicit statistically significant data, specific trends in attitude and practice did emerge. The survey revealed that 15 (19%) of the 77 non-Medicaid patients seen during the month of the initial sampling were not being charged a fee, despite the minimum fee of $3 per visit as determined by the sliding scale schedule. These no-fee patients contributed to the fact that the average estimated fees for second-year residents were more than triple the actual fees and the estimated fees for third-year residents were more than twice the actual fees.

All of the 14 residents on the service at a particular time were found to have at least 1 patient, and 4 residents had at least 4, who had not paid their set fees in over a month. One resident had 10 patients who were more than 6 weeks in arrears, with a balance totaling more than $400.

Among the attitudinal trends, 3 of the 20 residents stated a preference for treating patients receiving Medicaid to either no-fee or paying patients. One of these residents commented on not feeling "competent enough" to directly charge patients for therapy. A fourth resident preferred treating patients for whom there would be no fee at all. Three of these 4 residents who preferred no direct reimbursement also preferred having the receptionist set the fee rather than assuming this responsibility themselves. Of the other 16 residents who preferred fee-paying patients, 15 preferred to determine their patients' fees themselves. Nevertheless, 19 of the 20 residents studied still preferred that fees be collected by the receptionist.

Despite the sliding scale schedule and the clinic policy that fees be determined by the patient's financial situation, 4 residents felt that their fees should be lower than those of the nontrainee staff, 4 felt that with each year of experience a trainee's fees should increase, and 4 felt that residents' fees should be higher than those of trainees in other disciplines. Finally, there was a universal and gross underestimation of the clinic's reimbursement rate from Medicaid.

DISCUSSION

The study did confirm the hypothesis that there are conflicts and inconsistencies in residents' attitudes toward psychotherapy fees. The trends toward unawareness and avoidance of financial issues were reflected by the fact that all of the residents grossly overestimated their average fees and all had at least 1 patient who had not made payments in over 30 days.

It is interesting that while 15 of the 16 residents preferring fee-paying patients wished to set their own fees, 19 of the 20 residents surveyed preferred having the receptionist collect the actual fee set. This apparent paradox may be due in part to the clinic policy, which encourages therapists to set their own fees. It is enhanced by a dynamic phenomenon that makes it more comfortable to set a fee with a patient than to collect it. Given an option, 95% of the residents chose to delegate the latter responsibility.

The attitudes and practices demonstrated by this study point to the administrative, educational, and clinical difficulties involved in clinic management at a training facility. The suggestion is that the best mechanism to deal with these issues is an educational approach. Particular emphasis must be placed on the myriad transference-countertransference aspects of the patient-therapist financial interaction. One common example is the patient who needs to be indebted and who may resent the sense of bondage while simultaneously receiving sadomasochistic gratification. Obviously, the patient may be simultaneously expressing conscious appreciation for the therapist's "indulgence." Nevertheless, transference and countertransference feelings increase as the debt mounts until the patient discards the manipulated and denigrated therapist or the therapist's own anger at feeling controlled surfaces in an abrupt ultimatum resulting in the termination of therapy.

Another possible interaction is the patient's acting out, in collusion with the therapist, of a wish to cheat the clinic through nonpayment or underpayment. This phenomenon is common in the treatment of patients with sociopathic difficulties. The dynamics often involve an unconscious wish to be nurtured by the therapist-mother and the related acting out of the need to feel special. These reactions are more common in patients who have suffered early maternal deprivation, are narcissistic, and have characteristics of the "psychology of the exception" (4). Gedo (5) has conceptualized nonpayment in a somewhat different way. He sees it as often being a manifestation of a transitional

phenomenon in that the unpaid money becomes an intermediate link between the "me" patient and the "not me" therapist.

Finally, a common syndrome exists in which patients use residents' countertransference rescue fantasies or guilt about money for the purpose of blackmailing them to remain silent about financial issues.

The important and central theoretical and clinical points here are that regardless of meaning, when a patient directly or indirectly refuses to pay an appropriate fee and the therapist ignores this the two are mutually denying a significant piece of reality and the therapy is sabotaged.

Issues related to the technical management of financial aspects of the resident-patient relationship should certainly be the subject of discussion during supervisory sessions. (The question of personal therapy for residents and its effect on their practice is also relevant here.) Nevertheless, the mutual denial by patient and therapist that there is such an issue undermines the supervision and thereby the patient's treatment.

CONCLUSIONS

This survey confirmed the impression that psychiatric residents tend to avoid the monetary aspects of psychotherapy. Educators can play a significant role in both the improvement of training clinic finances and the broadening of resident growth by more actively addressing themselves to this area.

Inspiration of Psychotherapists by Patients

BY EDWARD MESSNER, M.D.

Many patients possess such exemplary traits and virtues that their psychotherapists are inspired to emulate them. This process can benefit the clinician and reinforce the therapeutic alliance, rapport, and the spirit of reciprocity; however, it can also arouse responses by the clinician that are therapeutically detrimental. Awareness of this hazard can enable the clinician to avert it and enhance the benefits provided by the patient's outstanding strengths.

MANY PATIENTS possess splendid traits of character and exceptional qualities of personality. The psychotherapists who encounter these exemplary features may adopt them as models for their own behavior. They can evoke in the therapist a degree of admiration and respect leading to a conscious desire to acquire the patient's virtues.

Examples of such traits are loyalty; perseverance in overcoming personal handicaps; energy, determination, and effort in pursuing a goal; verbalization and vocalization of intense emotion while forbearing from enactment of their corresponding impulses; and dignity in meeting enormous stress. Every experienced clinician could probably compile a similar list.

RELATED PHENOMENA

Although countertransference, identification, and learning may occur along with inspiration, they are different processes. Countertransference is a therapist's emotional response or reaction to a patient that is not entirely conscious and includes some elements inappropriate to their current relationship (1, 2). Identification is a form of automatic modeling or imitation, the most significant elements of which are not available to consciousness (2). Learning is a process of acquisition

Dr. Messner is Assistant Clinical Professor of Psychiatry, Harvard Medical School, and Associate Psychiatrist, Massachusetts General Hospital, Boston, Mass. Address reprint requests to Dr. Messner at Zero Emerson Place, Boston, Mass. 02114.

of knowledge, skills, or concepts. Inspiration, in contrast, is a process that is largely available to consciousness and includes strong elements of motivation, energy, and desire. The phenomenon of inspiration of the therapist may be classified as part of the nontransference aspect of the relationship with the patient (3). It is also one of the psychotherapist's sources of personal enrichment and development (4).

I reviewed the literature on countertransference and other subjective experiences of psychotherapists, covering approximately 70 publications from 1924 to 1976, and found no reference to the phenomenon of inspiration of the therapist by the patient.

CLINICAL CONSIDERATIONS

One of my patients, a man who developed a severely crippling physical handicap in childhood, exerted enormous effort to become autonomous and competent. Eventually he not only became the source of financial support for his impoverished family but also provided encouragement and love. I had not previously encountered, directly, anyone who had accomplished so much after starting with so little. His determination was immense. I discovered that I wanted to build my capacity for steadfastness and perseverance to his level.

My admiration for this patient showed in several ways, including nonverbally. Initially, it was helpful to him while he was depressed. Later it became a threat. Admiration was associated with warmth, warmth with closeness, and closeness evoked the spectre of loss. Loss and bereavement were crucial to the problems that had brought him to therapy. Consequently, my profound respect served to complicate the therapy.

Following my recognition of the countertherapeutic effects of my admiration, we were able to discuss it explicitly. This impediment to progress subsided, and he moved ahead even more. He developed the ability to receive as well as to give. He was eventually able to gain satisfaction from close personal relationships and from greater acceptance of himself. Favorable effects of therapy were evidenced by the patient's own observations, several events and relationships in his life, my opinion (obviously vulnerable to bias), and the views of an important relative who loved him but saw him only occasionally because of geographical separation.

COMMENT

The inspirational experience may be beneficial to the therapy as well as to the therapist. It can serve to strengthen the therapeutic alliance. It can also reinforce the emotional atmosphere of reciprocity and togetherness (4). In these ways it may reflect favorably on the patient.

In other ways the inspirational experience may prove detrimental to the patient. It can provoke a sequence of gratitude, obligation, and resentment in the therapist. In some clinicians, it can stimulate rivalry with the patient. It can also arouse feelings of admiration in the therapist that may lead to unfounded expectations of strengths in other areas of the patient's personality. In addition, inappropriate application of these standards of conduct and character to other patients may have an adverse impact. The inspirational virtues may also arouse envy and defensive comparisons in the clinician. This might lead him to emphasize, inappropriately, his own superiority in other areas.

This article was reviewed in preparation by Dr. Aaron Lazare, an Associate Professor of Psychiatry at Harvard Medical School and a skilled and experienced psychotherapist. Since the inspirational phenomenon is a part of many therapists' clinical experience, Dr. Lazare wondered why it has not been described previously. He conjectured,

> Perhaps in our role of therapists we are unwilling to acknowledge that we can be inspired by a patient or influenced by a patient in ways that cannot be explained by neurotic processes. How can a patient help us with personal enrichment and development other than by our being able to cure his neurosis or understand our countertransference difficulty? In sum, perhaps the patient's inspirational impact on us is too simple, too direct and too threatening to our role for us to see it. We may, then, react in ways that might prove detrimental to the patient. (5)

CONCLUSIONS

Psychotherapists need to be alerted to the appearance of inspiration just as they must with other clinical phenomena such as countertransference, transference, and identification. Particularly at times of difficulty in therapy—e.g., periods of turmoil or of stagnation—the clinician might do well to include inspiration in his mental checklist of possible causative factors. The clinician's awareness of hazards offers the possibility that they will be anticipated, neutralized, or overcome. Similarly, the beneficial effects of the inspiring virtues can be shared, reflected to the source, expanded, and enhanced.

Patient and Staff Reactions to a Strike by Essential Hospital Employees

BY GEORGE L. HOGBEN, M.D., AND ROBERT SHULMAN, M.D.

The authors sampled the feelings and attitudes of patients and staff toward an 8-day strike by 2,500 health care employees of a metropolitan hospital. The strike had a major impact, and most respondents felt angry at one of the parties of the strike. Sympathies toward the strikers and the hospital management were equally divided.

ON NOVEMBER 5, 1973, District 1199 of the National Union of Hospital and Health Care Employees conducted a strike against 40 hospitals and nursing homes in New York City. This action removed 2,500 of the 4,800 full-time employees from the Mount Sinai Hospital, a 1,100-bed voluntary hospital. The operation of the hospital was severely jeopardized as a result of the strike by employees from service, maintenance, technical, clerical, and professional groups. Striking workers included practical nurses, nursing aides, food handlers, patient-transport personnel, janitorial staff, engineers, operating room and laboratory technicians, and clerical staff.

The hospital management estimated that emergency planning could maintain curtailed hospital functions for 10 days. The hospital was closed for all admissions except extreme emergency cases, and a 100-patient-per-day discharge rate was established. All nonprofessional support personnel were redeployed to staff direct patient services. Volunteers were also placed into vital service and support areas. The professional staff established a shift plan, and all leave and days off were cancelled. Implementation of the plan required the availability of essential supplies and the maintenance of staff and patient morale. Sufficient quantities of food and patient-care items were stockpiled. Oxygen was delivered without incident. Oil deliveries were slowed, however, and most deliveries were made under angry verbal protest by the strikers.

Initially, morale among the patients and staff was high. Everyone expected a speedy end to the strike, and a romanticized feeling pervaded the hospital. However, during the third day of the strike it became obvious that negotiations would be prolonged. The already intricate bargaining between labor and management was further complicated by the involvement of the Cost of Living Council as a third party. The Council had been established by the federal government to review the fiscal aspects of all contract settlements. Gradually the mood became grim, tense, and resigned. These feelings prevailed through the remaining 5 days of the strike. The negotiated settlement was completed on November 13, just 3 hours before the last oil supplies would have been exhausted.

This paper reports an attempt to systematically sample the feelings and attitudes of the staff and patients during the strike.

At the time this work was done the authors were with the Mount Sinai School of Medicine of the City University of New York, Fifth Ave. and 100th St., New York, N.Y. 10029, where Dr. Hogben is Assistant Professor of Psychiatry and Dr. Shulman was a third-year medical student. Dr. Shulman is now a first-year medical resident, Newton-Wellesley Hospital, Newton Lower Falls, Mass.

METHOD

The decision to formally question staff and patients was made on the third day of the strike when the overly optimistic mood seemed to change. Separate staff and patient questionnaires were devised to survey feelings and attitudes about the situation and the participants in the strike. The questionnaires were administered during the fifth and sixth days of the strike. Medical and psychiatric ward patients who were not disoriented were asked to complete the questionnaire; mechanical aid was provided for patients who could not write. Staff and volunteers were canvassed from desks in the hospital cafeteria at lunch and dinner meals. These procedures produced 32 completed patient questionnaires, representing about 40% of the medical and psychiatric ward population at the time of the study. Sixty-one staff questionnaires were completed.

RESULTS AND DISCUSSION

Table 1 presents the results of patient and staff responses to the questionnaire. The strike had a major impact on the hospital milieu. Sixty-seven percent of the patients and 72% of the staff felt the situation was extremely or considerably serious, 33% of the patients and 28% of the staff felt it was moderately serious, and none of the respondents viewed the situation as mildly or not at all serious.

Sympathies toward the strikers and the hospital management appeared about equally divided. Of the

TABLE 1
Patient and Staff Reactions to the Hospital Strike, in Percents

Questionnaire Item	Patients (N=32)			Staff (N=61)		
	Yes	Not Sure	No	Yes	Not Sure	No
Sympathetic with strike	58	10	32	64	13	23
Sympathetic with strikers	45	32	23	59	22	19
Angry at strikers	39	11	50	12	21	67
Afraid of being hurt	13	3	84	23	14	60
Afraid visitors will be hurt	42	19	39	—	—	—
Want to leave the hospital	44	3	53	7	2	91
Sad about the strike	70	7	23	76	7	17
Afraid patient care will suffer	28	9	63	78	3	19
Avoid strikers by entering door where none are present	—	—	—	41	8	51
Sympathetic with people entering the hospital	73	13	13	—	—	—
Angry at hospital management	19	9	72	16	9	76
Sympathetic with hospital management	40	13	47	50	29	21
Angry at Cost of Living Council	84	13	3	85	8	7
Sympathetic with Cost of Living Council	0	23	77	0	2	98
Tell strikers to maintain strike	—	—	—	19	12	69
Tell strikers to end strike	—	—	—	19	19	62

staff, over one-half expressed sympathy for the strike and the strikers, and half sympathized with the hospital management. Surprisingly, since their health could be adversely affected by the strike, over one-half of the patients expressed sympathy for the strike, and slightly less than half sympathized with the strikers and the hospital management. Moral and ethical arguments against strikes by health care workers were frequently verbalized during the strike, and official reactions to it were generally unsympathetic. However, the sympathetic reactions of the patients indicate that one-half of the health care consumers sampled in this study did not share the authorities' opinions about it.

The strike action seemed to stimulate angry feelings in most of the patients and staff. Eighty-four percent of the patients and 85% of the staff expressed anger at the Cost of Living Council, 39% of the patients and 12% of the staff at the strikers, and 19% of the patients and 16% of the staff at the hospital management. These findings emphasized the somewhat unusual circumstances created by the direct intervention of the federal government in the strike. While the Cost of Living Council seemed to forestall an earlier termination of the strike, it may well have acted as a focus for hostile feelings and thus have aided in the relatively smooth relationship observed among strikers, staff, and patients. Twenty-three percent of the staff and 13% of the patients were afraid of being hurt by violence. Only 7% of the staff wanted to avoid the strike by leaving the hospital, but 41% wanted to avoid the strikers by entering a door where no strikers were present.

There were no reports of untoward patient care incidents resulting from the strike. However, the patients and staff had different perceptions about the quality of care being delivered during the strike. Thirty-five percent of the staff, compared with only 13% of the patients, felt that patient care was better during the strike. On the other hand, 44% of the patients and 26% of the staff felt that care was not as good as it had been before the strike. The rest of the patients and staff felt that patient care was the same as before. Apparently, receiving care during the serious situation created by the strike reduced the patients' worry that quality of care would suffer, since only 28% expressed this fear. This response is in striking contrast to that of the staff. Seventy-eight percent were afraid patient care would suffer, which suggests that staff members were quite concerned about their abilities to discharge their responsibilities for patients in a crisis situation.

A review of the literature indicated that no data were available about reactions to the few earlier strikes by health care workers in New York City and elsewhere in the country, and thus it was not possible to determine whether the reactions expressed during this strike represented a change in feelings and attitudes about strikes in the health field.

LETTERS TO THE EDITOR

A Reply to a Rebuttal

SIR: I appreciate the opportunity to react to Dr. Kety's response (1) to my commentary (2) on his study of genetics and schizophrenia (October 1976 issue).

Dr. Kety suggests that I have engaged in careless reading of his papers, and documents this suggestion with excerpts from my critique, followed by "answers" from his papers. He opens this documentation of careless reading with a reference to my complaint about having had to guess which statistical test had been used to analyze the data. Dr. Kety suggests that the test was specified by the phrase "p, one sided probability from exact distribution=0.0072" (1, p. 1134). Many readers will join me in wondering *which* exact distribution—multinomial? binomial? Poisson? Fisher's?

Although only readers with a high energy level, high interest, and freedom from "statisticophobia" will check Dr. Kety's "rebuttal" of my position point by point, I would like to offer three guidelines for those who do examine our exchange in detail.

1. Follow carefully the specific references cited under Dr. Kety's heading, "our paper." My commentary applied only to his original study, which contained carefully imposed controls on defining schizophrenics. However, several of the rebuttals come from a subsequent expansion of the original study that added schizophrenic subjects defined on the basis of one interview conducted by one of the authors. I did not and will not now consider this expanded study in my arguments.

2. Note that there was no direct response to my objection that, when all the detail and statistical hocus-pocus is boiled away, the main finding is that the major difference between index and control families occurred in the half-sibling category; thus, the weaker the consanguinity, the greater the "genetic" effect. Dr. Kety appears to respond to this objection with the observation that schizophrenic subjects are more than normally vulnerable to infertility, abortion, and suicide; these factors, he reasons, make it less likely that a diagnosis of schizophrenia would be found in the parent category than in the half-sibling category. One can see how these factors (not to mention divorce) might affect the sibling category but not the parent category as defined in the first study, in which the schizophrenic adoptees studied had obviously already survived the possible problems of parental infertility and abortion. Suicide would not have precluded tagging parental schizophrenia because the diagnosis was made through the population register and hospital records; interviewing living parents was not required. One does need to presume that parental schizophrenia did not *first* appear as suicide, that is, the parent would have had to manifest schizophrenic behaviors to a degree sufficient to establish the diagnosis of schizophrenia before committing suicide. Dr. Kety's original paper indicated that 63 biological parents were located for both the 33 index cases and the 33 control cases. Given this comparability of numbers, and presuming that schizophrenia is rarely initially manifested as suicide, it is reasonable to conclude that the samples of parents for index and control subjects were comparable in availability.

3. Note that my general methodological comment about the research design was transformed by Dr. Kety into a position in favor of an SES interpretation of schizophrenic, which he then refuted. However, my comments on socially adaptive attributes were intended to address Dr. Kety's theme that schizophrenia is associated with a destructive "illness" gene. If this idea is pursued it is important to establish whether contrasts between index and control groups were due to superiority of the control group and/or to inferiority of the index group. One does not need Dr. Kety's additional observations (1, p. 1135) about how many cases were born of married couples to refute a social adaptation interpretation of the half-sibling findings. Moreover, I commented, "this formulation, like the genetic (disadvantage) interpretation, falters because of the failure to find differences between index and control parents. Thus the argument remains at a stalemate" (2, p. 1132).

In spite of Dr. Kety's suggestions of careless reading and invoking of additional information, the fact remains that applying a statistical test which does not violate the independence assumption to the results obtained from the original carefully controlled samples shows that significant differences occurred only in the half-sibling category. Because the parent category did not show a difference between index and control groups, the results cannot be explained by either the genetic advantage (control) or genetic disadvantage (index) hypothesis; nor does a reasonable environmental hypothesis account for the peculiar findings. All we know at present is that a relatively small sample of adoptees showed an understandably high proportion of half-siblings and significantly more half-siblings of the index group had schizophrenia.

On Sexism in the Language

SIR: I have noticed that many authors in the *Journal* have tried to be nonsexist in their use of pronouns. For example, by using "he or she" to describe psychiatrists, authors at-

tempt to avoid the linguistic stereotypes that are rampant in medicine (1).

Unfortunately, phrases such as "he or she," "him/her," "she/he " etc., are extremely awkward to use, especially in speech. The English language has no singular pronouns that encompass both sexes.

Farrell (2) has suggested an alternative, the following "human pronouns," which should become part of the language: 1) "te" (pronounced like "tea") for he or she, 2) "tes" for his or her, and 3) "tir" (rhymes with "her") for him or her.

In addition to avoiding linguistic sexism, these words also have a consciousness-raising effect. Because they are new and unusual, hearing or reading them makes one stop and examine for "tirself" (himself or herself) how easy it is to fall into the trap of sexist use of the language.

It is my fervent hope that the "human pronouns" will be incorporated into the language. As clinicians, scientists, and teachers we can help this process by using these words in everyday conversation (it will take practice) and in the papers we publish.

Request for Information

SIR: I am attempting to collect copies of journal papers, magazine articles, news items, research projects, professional theses etc., related to the Robert Butler concept of life review. Related material dealing with reminiscing, group psychotherapy, dreams, legacies, and life histories would also be helpful.

I will be glad to send those who provide such information a copy of the bibliography I am compiling on this subject. Please send information to the address below. Thank you for your interest.

Failure of Deanol in Treating Tardive Dyskinesia

SIR: Neurological syndromes associated with the use of neuroleptic drugs in treating psychoses have justifiably caused much concern in recent years. Tardive dyskinesia has proved to be a particularly difficult condition to treat. Deanol is used in tardive dyskinesia on the premise that sustained dopaminergic blockade with antipsychotic agents results in an upset in the dopamine-acetylcholine balance in the basal ganglia and that deanol, a possible cholinergic precursor, may help restore the balance. We would like to report the cases of two patients with chronic tardive dyskinesia in whom deanol treatment was unsuccessful and, in one patient, produced severe side effects.

The first patient was an 89-year-old widower with a 50-year history of chronic psychotic illness diagnosed as paranoid schizophrenia. He had been hospitalized continuously since 1952 and had received hydrotherapy, insulin and electroconvulsive therapies, and numerous antipsychotic agents over the years. Severe orofacial dyskinesia (chewing, sucking, writhing tongue movements) with dyskinesia of arms and akathisia were first noted in 1972 during a hospital-wide neurological survey of all chronically hospitalized geriatric patients. The patient was taken off all neuroleptics for 6 months and from October 1973 on received the following medications: 6 mg/day of haloperidol for 2 months 4 mg/day of benztropine mesylate for 2 months, 20 mg/day of thioridazine for 3 months, 20 mg/day of thioridazine plus 450 mg/day of deanol for 2 months, and 600 mg/day of deanol for 3 months, without any response in the severity of tardive dyskinesia. Further increase in deanol was not possible as the patient developed marked sialism (requiring several changes of shirts daily), bronchospasm, and parkinsonian rigidity. The patient has now been off all neuroleptic medication and deanol for over a year. Over the past 2 years there has been no change in the tardive dyskinesia.

The second patient is an 80-year-old widow who has been continuously hospitalized since January 1972, with a history of schizophrenic illness since 1943. She was treated with electroconvulsive and neuroleptic therapies. Moderately severe tardive dyskinesia affecting lips and tongue, continuous chewing movements aggravated by anxiety, and parkinsonism were noted in November 1972. She was treated with 15 mg/day of chlorazepate dipotassium for 6 months with some improvement, but the tardive dyskinesia returned to the same level of severity when the chlorazepate dipotassium was discontinued. She has been off all neuroleptic medication since 1973. In May 1975, she was started on deanol in gradually increasing dosages up to 800 mg/day. She received deanol for 5 months without any change in her tardive dyskinesia. Over 4 years the tardive dyskinesia has not been progressive.

It may be argued that these patients did not receive large enough doses of deanol. It is also possible that they had neurological dysfunction of an irreversible although nonprogressive nature and that age and chronicity are important factors in therapeutic response. Tardive dyskinesia of milder degree and shorter duration may be more amenable to deanol treatment. In increasing the dose, cholinergic side effects such as salivation, bronchospasm, and parkinsonian rigidity ought to be noted. Controlled studies in the treatment of tardive dyskinesia are urgently needed.

More "Craft Versus Science"

SIR: One of the most stimulating things about the article "The Future of Alcohology: Craft or Science?" by Melvyn Kalb, Ph.D., and Morton S. Propper, M.S.W. (June 1976 issue) is that its publication will most assuredly precipitate discussion of the "conflicts and friction between the professionals and paraprofessionals" that the authors feel "have not been allowed to surface."

The article does contain two flaws. First, there is a total lack of historical perspective. If the authors had gone back to the period of 1840 to 1860, they would have found lay and religious groups entangled in the care of the "insane" and

those afflicted with "consumption," and woe to any physician who spoke against either the "moral treatment of the insane" or the doctrine of "fresh air" for what we now know as tuberculosis.

Physicians typically arrive at the scene of a health problem and find some nonprofessional individual or group in charge. If the problem has been neglected for decades, the physician will find a group of crusaders, some of whom will be "exes," caring for the ill according to some simplistic doctrine, be it "fresh air" or "don't take the first drink."

To look at the evaluation of the treatment of the mentally ill and the tuberculous patient and then to predicate a rigid dichotomy of craft or science for alcoholism is to ignore history to the point of being foolish. Ex-alcoholics were there before we arrived on the scene. Some of them are highly trained physicians, like the ex-tuberculous physicians who taught me, and are capable of analyzing sophisticated research data and translating this into training material for the paraprofessional.

The ex-alcoholic of 1976 is not the ravaged person of 1946. He or she might be someone with a master's degree working on a doctoral degree, all since having stopped drinking. The possibility that it might be necessary to employ an ex-alcoholic with no special training in the field is becoming less and less common. Describing the ex-alcoholic as some sort of unintelligent lout clinging to misguided notions about alcoholism and totally oblivious to new information is a bit off the mark.

I have many serious concerns about the alcoholism field as I watch it repeat the history of the mental health movement of the 1950s and 1960s, but the domination of paraprofessionals over professionals is an issue that, while real in some areas, is not having an unusually harmful effect on treatment. The field of alcoholism is moving down its tributary into the mainstream of the health care delivery system. Who the captain of the ship will be is still in doubt, but one of his/her qualifications will not be to have been an alcoholic.

THOMAS T. FLYNN, M.D.
Jefferson City, Mo.

Dr. Kalb and Mr. Propper Reply

SIR: It seems that Dr. Flynn is criticizing us for not having written an entirely different article. Insofar as we are able to discern the issues in his letter, Dr. Flynn seems to assert that a historical perspective would reveal that the current situation in the field of alcoholism is an analogue of the early development of a scientific problem-solving enterprise. He also seems to have misperceived our paper as an attack on the character and intelligence of recovered alcoholics.

The struggle over "moral therapy" referred to by Dr. Flynn was an extremely complicated issue that marked the infancy of modern psychiatry. We do not believe it is reasonable to argue that the struggles and conflicts that characterized the infancy of psychiatry as a scientific enterprise should be accepted as the norm for the current level of dialogue regarding serious problems in the field of alcoholism. If anything, the similarities between the acrimonious political machinations that characterized the struggle over the treatment of the "insane" in the 1800s and the ferment in the 1970s over the role of scientific research in clinical alcohology tend to underscore the very problem discussed in our article.

Dr. Flynn makes unsupported assertions concerning the differential characteristics of "ex-alcoholics" in the 1850s, the 1940s, and the present. Apparently these assertions are meant as a response to some imagined denigration of the "ex-alcoholic" paraprofessional in our paper. We most earnestly disavow any such implications. Our article in no way attempted to evaluate the present clinical effectiveness of the paraprofessional in the alcoholism treatment field.

Finally, Dr. Flynn states, "the domination of paraprofessionals over professionals is an issue that, while real in some areas, is not having an unusually harmful effect on treatment." Our entire article was a documented refutation of this premise.

MELVYN KALB, PH.D.
MORTON S. PROPPER, M.S.W.
Sunnyvale, Calif.

Correlation or Causation: Neuropathophysiology and Autism

SIR: In "The Syndrome of Autism: A Critical Review" (June 1976 issue) Edward M. Ornitz, M.D., and Edward R. Ritvo, M.D., provided a good review of current research, but they also made several assumptions about autism and the early childhood psychoses that are unwarranted by the clinical and research evidence presented. If these assumptions are accepted, they may inhibit important lines of more psychodynamically oriented research and treatment.

The authors' foremost unwarranted assertion is that "symptoms [of autism] are expressive of an underlying neuropathophysiologic process." This statement suggests that a neuropathophysiologic process is etiologic. I wish we could know this with certainty, but unfortunately the data cited derive almost entirely from studies of children who have been living with the stress of the psychosis for months and years. It is reasonable that these stresses and other secondary effects of the illness may produce the deviations from normal on the parameters studied. A striking example of how this can occur is the recently identified syndrome of idiopathic hypopituitary dwarfism (1), in which children who have experienced emotional deprivation and physical abuse and often have lived in many different foster homes were found to have bizarre behavior (including stereotypies) and short stature, with depressed pituitary function and growth hormone levels that rebounded with emotionally nurturing hospitalization.

Thus it would be more accurate to present the research findings the authors reviewed as correlations with autism from which we can only draw inferences to be tested. Drs. Ornitz and Ritvo also stated that "no known factors in the psychological environment of a child can cause autism." I recently reported a case in which home movies showed a mother repeatedly turning the infant's face and eyes away from hers (2). From 6 months on this child developed the classical autistic picture. This is a kind of specific traumatic interference with biologically rooted attachment that is not necessarily etiologic of autism but is correlated with it.

A third area inadequately discussed by Drs. Ornitz and Ritvo is the potential explanatory power of the intrapsychic experience of autistic children for some of the behavioral symptoms. For example, some stereotypies and motility disturbances can be well explained by inferring autoerotic stimulation and defective body image instead of or as well as inferring an underlying pathophysiologic disturbance. Whatever the cause of autism, the authors omit the importance of trying to understand the child's intrapsychic experience in

framing treatment, which is the psychiatrist's unique area of expertise. In sum, the article is a valuable review of highly important and potentially fruitful avenues of research, but it must be read very critically.

HENRY N. MASSIE, M.D.
San Francisco, Calif.

Drs. Ornitz and Ritvo Reply

SIR: We heartily agree that a critical reading should be given to any review. This is particularly true of a "critical review," wherein authors may all too easily not only exercise their scientific judgments but also espouse their prejudices.

We also appreciate Dr. Massie's calling our attention to the fact that we had not been explicit enough in labeling one of our chief "working hypotheses" as such. Thus, Dr. Massie formed the opinion that our "foremost unwarranted assumption ' is that autism's symptoms are expressive of an underlying neuropathophysiologic process. Apparently we did not sufficiently emphasize that this was simply a working hypothesis, not our assertion. For the record, we would like to quote our article, with emphasis added: "The current state of our *medical art* leads *us* to the following conclusion" (p. 618), and

> Figure 1 shows the *possible* etiological and phenomenological interrelationships among the clinically and behaviorally defined syndromes of autism, primary cognitive and intellectual retardation, and psychologically induced psychoses (severe ego pathology). This *model* is based on the *hypothesis* that the syndrome of autism results from CNS pathology of a specific type. This neuropathophysiology may occur on an idiopathic basis or in *conjunction* with specific diseases of known etiology that affect the CNS.

We would also like to comment on Dr. Massie's opinion that we inadequately discussed the "potentional explanatory power of the intrapsychic experience of autistic children for some of the behavioral symptoms." This was done purposely. As stated in our conclusions, "we have tried to survey those studies which were based upon serious scientific efforts and avoid those which simply expressed opinions" (p. 618). No one is more distressed than we (having both devoted many years to psychoanalytic training and to the treatment of psychotic children by psychodynamically based psychotherapy) that theories of intrapsychic and interpsychic experiences of autistic children remain in the realm of opinion. Unfortunately, they have not led, to our knowledge, to operationally defined hypotheses that have been tested by generally accepted scientific methods.

Dr. Massie noted that we did not review his study and commented on a similar study regarding hypopituitary dwarfism. We were aware of Dr. Massie's work, but we considered the cited references as case reports or pilot projects, which although heuristically valuable were not cited in our article (including our own pilot projects).

We do not wish ourselves, our students, or our readers to be polarized into obfuscatory controversies between "organicists" and "psychogeneticists" regarding the etiology of complex syndromes such as autism. Scientific understanding is achieved only by maintaining intellectual and emotional objectivity, establishing hypotheses, and conducting experiments to determine their validity. Determination of the etiologies of complex syndromes such as autism will not be reached by a single experiment, a series of experiments in one area, or, least of all, by opinionated debates. The answers will come only from diligent scientific investigations from varied perspectives accumulating evidence that stands the test of time, both by replication and by clinical experience. We say "answers" because, when we speak of autism, we must bear in mind that we are dealing with a behaviorally defined syndrome that clinical experience indicates can accompany (or be correlated with) many events. That such events may or may not be etiologic is a point on which we certainly agree with Dr. Massie.

The future holds the answers. Hopefully, humanistic zeal and faithful adherence to the principles of scientific investigation will provide therapies to help our unfortunate patients and their equally unfortunate families.

EDWARD M. ORNITZ, M.D.
EDWARD R. RITVO, M.D.
Los Angeles, Calif.

Organic Brain Dysfunction and Personality Disorder

SIR: I would like to question the conclusions reached by Paul C. Horton, M.D., in "Personality Disorder and Parietal Lobe Dysfunction" (July 1976 issue). Dr. Horton attempts to reason by analogy between phenomena unquestionably characteristic of parietal lobe dysfunction and phenomena he alleges to be characteristic of personality disorder. The "hypothesis" he reaches by this reasoning is that there exists a "relationship between personality disorder and nondominant parietal dysfunction." I would suggest that the phenomena alleged to be part of personality disorder are not present and that, consequently, Dr. Horton's analogies break down, leaving his hypothesis without support.

His first analogy is between constructional apraxia, characteristic of parietal lobe dysfunction, and an alleged inability of patients with personality disorders to "relate transitionally." He goes on to intimate that the ability to relate transitionally consists of two parts: the ability to experience a phenomenon as "soothing," and the ability to "personalize and make an external object such as a blanket or a teddy bear internally meaningful." Clearly, as the author does not state that patients with parietal lobe dysfunction have an inability to be soothed, the proposed analogy here must be to the inability to personalize (except, perhaps, in those with borderline personality disorder). Such patients often have quite stable mental representations, which readily undergo projection, leading in turn to personalization of external phenomena. Unfortunately for these patients, however, their mental representations are often felt to be unloving and/or cruel, and thus "personalized" phenomena are perceived as fearful, not soothing. Although I believe that the inability to be soothed is characteristic of personality disorder, I do not think that the alleged inability to "personalize" is present in personality disorder; thus, this analogy breaks down.

The second analogy is between the anosognosia character-

istic of parietal lobe dysfunction and a "lack of awareness" of illness in personality disorder, which is allegedly unrelated to psychological conflict and "rigidly" resistant to "vigorous conventional psychological approaches." I agree that patients with personality disorder lack awareness, but I do not believe that such a deficit is irreversible or unrelated to intrapsychic conflict. I believe that, although it is difficult, such patients may be brought to an awareness of their illness. Consequently, I think this second analogy breaks down and thus, deprived of support, the author's conclusion that there exists a relationship between personality disorder and parietal dysfunction should be viewed with skepticism.

My purpose in making this argument is twofold. First, I wish to caution others about making an implausible connection between organic brain dysfunction and personality disorder. Second, and most important, I hope to keep others from lending credence to the dismal correlary that patients with personality disorder are truly ill in a neurologic sense and thus not amenable to anything but supportive psychotherapy.

DAVID P. ROHMANN-MOORE, M.D.
Madison, Wis.

SIR: Dr. Horton's article was quite informative and provided much theoretical material worth exploring. However, I take exception to his implication that he has discovered the sine qua non of all personality disorders in a particular brain syndrome.

In effect, the article posits causal connections between parietal lobe dysfunction and the absence of "transitional relatedness" and between the absence of transitional relatedness and the presence of personality disorder. In support of the former connection, Dr. Horton notes that the nondominant parietal lobe is known to handle some functions that would seem to be important in developing transitional relatedness. Regarding the latter relationship, he speculates that if a person lacked transitional relatedness, he might be expected to exhibit symptoms similar to those of personality disorders. Finally, he notes that patients with parietal lobe dysfunction are known to have some of the symptoms of personality disorders, notably lack of insight. Taken together, these observations furnish presumptive evidence for the inference that a person born with a parietal lobe dysfunction is, under certain other conditions, likely to develop some personality disorder. However, the conclusion that the brain disorder is a necessary condition for personality disorder is simply not warranted.

Clinical evidence supporting a link between transitional relatedness and personality disorders has been in general isolated and anecdotal (1). Much of the literature on specific personality disorders actually tends to contravene Dr. Horton's theory. For example, hysterical personalities are noted for their "pseudo-insight" (2). This would seem inconsistent with an organically determined anosognosia, which implies a perseverating denial of problems, while "pseudo-insight" suggests a shallowness or inconsistency in recognizing them. A more serious difficulty is presented by the obsessive patient who, if anything, experiences a pathological *excess* of transitional relatedness (3).

More generally, one may question the propriety of accepting a tenuous diagnostic linkage between a specific neurologic problem and a disorder that is primarily defined through interpersonal coping strategies. I have come across few data in either the diagnostic literature or clinical records that suggest a marked prevalence of chronic disorientation (or associated perceptual problems) among personality disorders, as one would expect with a parietal lobe dysfunction. More to the point, in the section on personality disorders, *DSM-II* (4) specifically prescribes that when "the pathological pattern is determined primarily by the malfunctioning of the brain, such cases should be classified under one of the non-psychotic organic brain syndromes rather than here."

While the phenomenon of transitional relatedness (and its possible organic homologies) is certainly worth investigating as a potential etiologic factor in personality disorders, both our present diagnostic system and the present level of clinical evidence militate against accepting any sweeping hypothesis like that proposed in Dr. Horton's article: "An inability or incapacity for transitional relatedness [with its locus in the right hemisphere] is the psychopathological cornerstone, the necessary . . . condition of personality disorder."

ROBERT E. ERARD
Washington, D.C.

Dr. Horton Replies

SIR: My thanks to Dr. Rohmann-Moore and Mr. Erard for their comments. Unfortunately, space does not permit a response to all of the issues they have raised.

My article showed isomorphism between salient features of personality disorder and minor parietal lobe dysfunction. Misunderstandings arise if one equates "isomorphic" with "reducible to" and subscribes to the traditional medical perspective that asserts the ubiquitous primacy of cerebral processes (1). We have described the sine qua non of personality disorder as the virtual inability for transitional relatedness (2)—not simply and reductionistically as a disorder of the parietal lobe. There is, in my opinion, much to support the postulation of a specific cerebral cause for well-defined personality disorder. However, the genesis of transitional relatedness, particularly during the first few years of life, requires more study before conclusions can be reached. Coppolillo (3), for example, has described how a mother may impede development of transitional relatedness.

Evidence for a link between personality disorder and inability to relate transitionally is good (2) but not widely appreciated for two reasons. First, the concept of transitional phenomena has yet to find its way into most psychiatric textbooks. The latest edition of the *Comprehensive Textbook of Psychiatry* (4) does not even mention the concept. Second, my associates and I are the first, to my knowledge, to explore the relationship between personality disorder and transitional relatedness. We invite replication. Interested researchers should carefully observe the strictures of *DSM-II* for diagnosis of personality disorder, especially with respect to "deeply ingrained maladaptive patterns of behavior that

are *perceptibly different in quality from psychotic and neurotic symptoms*" (emphasis added). For example, the acting-out but voluntary patient with a "character neurosis" seen in a university outpatient clinic or in psychoanalysis should not be confused with the individual with an antisocial personality disorder seen in a military hospital or prison.

We have shown that those with well-defined personality disorders are unable to develop and sustain psychologically soothing experiences and modes of relating (2, 5). They treat their inner life as concretely and impersonally as they do that of others. Attempts to establish emotional closeness characteristically make them edgy, even panicky. The psychiatrist is hard pressed to find anything such patients regard as sacred and to which he can appeal in forming a working alliance. Some of these patients have a limited capacity for experience in this mode and can be helped to develop the ability. As they become more able to relate transitionally they begin to apprehend the nature and magnitude of their illness (5). Therefore, the likelihood that the unawareness of illness (anosognosia) shown by these patients is related to a primary cerebral disorder does not necessarily preclude experiential modification or compensation (1, 5).

To those who understand the concept of transitional relatedness and have worked extensively with well-defined and severe personality disorder, our hypotheses offer many opportunities for development and testing. For example, one could (if resources were available) compare cortical biopsies of tertiary zones of the minor parietal lobe from personality disordered patients with controls. A cortical aberration in these areas would be consistent with my hypothesis.

Feedback on the Boards

SIR: There is a hint of turbulence stirring in the psychiatric horizon, as is witnessed by recent letters and articles appearing in the *Journal* that address themselves to the issue of certification and recertification (1–4).

Whether specialty certification is even productive in regard to improving the quality of health care—a raison d'être of the specialty Board—is questioned by Dr. Chase (5), who feels the consequences of this certification may distort an objective view of "the conflict between what protects the public from incompetence and what serves the self-interest of declared certified specialists through exclusivity." Dr. Chase wonders if research could be directed toward finding viable alternatives to certification that would also promise improved specialty care.

Dr. Small (6), who is sympathetic to the Board and who has delineated many of the criticisms and challenges to it, has pointed out one specific criticism—the Board does not supply either adequate or useful feedback with regard to a candidate's performance in either the written or oral examinations regardless of the candidate's grade. The Board and their examinations are virtually a given *fait accompli*, since it is doubtful that viable alternatives to certification are close to hand; therefore, I believe that the Board should now respond to Dr. Small's criticism.

It is a well-established fact that feedback is an effective facilitator in learning, and it is unconscionable that the Board, which prides itself in establishing criteria for professional competence, does not point out the weaknesses and strengths of each of its candidates. It would seem a simple procedure, especially with the assistance of computer technology, for the Board to tell all candidates how they rank among their peers in the tested areas and to offer suggested readings in areas where deficiencies are noted in order to help the candidates improve their skills. This could be done in a way similar to that used in the Psychiatric Knowledge and Skills Assessment Program.

It may even be desirable to set a goal of, for example, 80% of all practicing psychiatrists to be certified, instead of the approximately 60% who took and passed the Boards in 1975. Useful feedback on both written and oral examinations could possibly improve psychiatry's standing in the certification numbers game as long as certification is still a sine qua non for recognized professional competence.

Editor's Note. We would like to point out that candidates can get feedback on the Boards by writing to Lester H. Rudy, M.D., Executive Director, American Board of Psychiatry and Neurology, Inc., 1603 Orington Ave., Suite 1320, Evanston, Ill. 60201. Feedback includes review of the outcome of the oral portion of the Boards as well as scores and quartiles on both portions of the written exam.

Patient Responsibility and "Free" Psychotherapy

SIR: The experiences reported by James L. Nash, M.D., and Jesse O. Cavenar, M.D., in "Free Psychotherapy: An Inquiry into Resistance" (September 1976 issue) invite comparison with the Canadian situation, where psychotherapy in private practice is free under universal Medicare. Clearly, in the absence of a fee-for-service social context, Medicare patients do not feel like charity cases. For most people, the

knowledge that the government pays the bills prevents a feeling of obligation.

How does the patient who would express his hostility by not paying his bills behave under Medicare? The only way he has to deprive the therapist of his fee is not to come; the government does not pay for missed sessions. Thus most psychiatrists here have made contracts with their patients that include responsibility for attending sessions. If they come, Medicare pays; if they miss sessions (for reasons other than illness or snowstorms), they are directly billed for the time.

Limit-setting of this nature also helps avoid countertransference difficulties, either the resentment of a therapist deprived of income or the need of a therapist to be "giving" by making no demands. Any patient in psychotherapy must meet certain minimum expectations; it is that and not the fee which is the issue.

LETTERS TO THE EDITOR are welcomed and will be published, if found suitable, as space permits. Like other material submitted for publication, they must be typewritten double-spaced. The letter should not exceed 500 words, including references, unless a special arrangement has been made with the Editor, and they will be subject to the usual editing. Receipt of letters will not ordinarily be acknowledged.

BOOK REVIEWS

Creativity: The Magic Synthesis, *by Silvano Arieti. New York, N.Y., Basic Books, 1976, 429 pp., $15.95.*

The mystery of the creative act has intrigued contemporary thinkers for decades. In this absorbing, thoughtful, and erudite volume Silvano Arieti addresses himself to this issue with vigor and conviction. After critically reviewing the major psychological and psychoanalytic theories of creativity, Arieti proposes his own hypothesis that the creative act encompasses a special ability to synthesize primary process mechanisms with secondary process mechanisms. For this special combination he proposes the term "tertiary process." Although Arieti has advanced this concept in previous articles in *The Intrapsychic Self* (1), he develops his thesis with much greater detail in this work, providing a wide-ranging and impressive discussion that encompasses wit, poetry, painting, music, religion, science, philosophy, and general systems theory.

The discussion of the relationship between creativity and the sociocultural environment is particularly interesting. In this section of the book Arieti addresses himself to the question of why geniuses or specially creative individuals appear at certain times in history, in certain places, and often in clusters. He concludes that a significant synthesis of cultural elements plays an important part in such historical occurrences, but he also points out that the work of genius requires an individual with special creative potential. "Actually," he says, "*the significant synthesis is the creative process itself.* It is so significant and unpredictable as to appear magic. Even when a culture is propitious, the significant synthesis occurs in a very small percentage of its people" (p. 302).

Arieti believes with others, however, that the *potential* for significant creativity is much more frequent than its occurrence. This leads him to a consideration of what he calls the "creativogenic society," that is, the kind of society that enhances creativity in its people. He lists nine sociocultural factors that characterize such societies and discusses the phenomenon of creativity among Jews in modern times as an example of how the creative potential of a group can be inhibited by unfavorable sociocultural circumstances and enhanced by favorable ones. Arieti also presents an eloquent and forceful argument against the traditional assumption that women are biologically inferior to men in the field of creativity, concluding with the following statement:

> The striking disparity in the creativity displayed by men and women should convince everybody, not of the alleged inferiority of women, but of the extent and degree to which women have been mistreated by society. It is fair to assume that, given equal status and opportunities, they would have contributed as much as men. (p. 318)

In the concluding sections of this stimulating volume the author discusses various personality attributes of the creative person and how individual creativity can be cultivated and promoted. Finally, he offers some interesting speculations about the neurology of creativity.

In short, in *Creativity* Arieti presents a thoroughly convincing study of the psychodynamic and sociodynamic factors that enter into the creative process, what he calls the "underlying structure of creativity." In the end, however, the actual source of the "magic synthesis" remains as mysterious as ever: "The creative person remains the keeper of the secret of what makes his personality creative—a secret that he cannot reveal to himself or to others" (p. 412).

JUDD MARMOR, M.D.
Los Angeles, Calif.

Knowledge in Action: Communication, Social Operations, and Management, *by Jurgen Ruesch. New York, N.Y., Jason Aronson, 1975, 342 pp., $15.00.*

Jurgen Ruesch, one of the world's experts in communication, has brought forth another book summarizing his methods and bringing his views up to date. His preface, dated August 1974, communicates the primary and secondary lags in the publication process.

I suppose it could be said that there has never been a time since the advent of the written word when a treatise on human interaction was not needed. We know for certain that ours is such a time. *Knowledge in Action* is therefore a timely book. One is unlikely to find a better guide for professionals and others who require the use of knowledge in action.

Man is being impinged upon constantly by communications of all sorts in an ever-increasing complex of people and machines. Almost everyone must perforce feel crowded by the system, particularly by government, by the unwieldiness of procedure of all sorts, and by "the ubiquitous and impersonal computer." How to sort out the material pouring in on us and put an immense knowledge into realistic action has been one of Ruesch's main concerns during his professional career.

Ruesch writes engagingly, and, although there is much of interest in the book, the specialist reader is apt to prefer one or another of the many areas discussed. As a teacher, I was particularly taken with the analysis of the professional versus the amateurish way of doing things (p. 270). Ruesch says that those who are eager to learn and who want to become professionals will readily accept a program of work and restrictions required for indoctrination. If the task is not essential, however, it hardly matters how it is done (the amateurish way), reflecting the fact that only a third of the total population works and only about a fifth of the population may be considered essential in running our civilization. The others are consumers for whom any curriculum can be lax and permissive.

Ruesch outlines the conceivable situations in which action is required as well as how they might be managed, including

making a nuisance of oneself to get some action on the part of an imponderable institution or bureaucracy, e.g., in interactions with computers when one is caught up in one of those automated billing systems. The analysis of transactions with bureaucracy and bureaucrats and of the social games that people play cannot but be helpful to anyone who must cope in these always unusual times.

Ruesch's statement that knowledge in action differs from knowledge in general (p. 302) reminded me of Kant's definition of faith: again and again it is necessary to make a decision on the basis of knowledge sufficient for action but insufficient to satisfy the intellect. Coping with and managing man and machine in our technological civilization is what this book is about. It is a first-rate treatise from which to garner assistance in communication and defining action. The author brings to the exposition a wide-ranging experience in communications, psychiatry, and education to assist people to engage in the right action.

The book is exceptionally well constructed; the typeface is pleasing and the paper is reflective. However, page 242 of my copy failed to print and was blank. The book includes appendices containing methods of procedure for exploration and acting and a glossary of terms. There is a bibiliography of more than 13 pages and a subject and author index of more than 9 pages.

Knowledge in Action could serve as an authoritative text in any of a number of college and secondary school programs. It might even function to break the bonds in the Lilliputian nightmare of forms and formulas. I recall that when we were on the same faculty Ruesch never tired of reminding me that the Roman Empire was run without paper. It is several decades later, and he continues to point a way to survival in the maze imposed on us by the times in which we live.

CHARLES D. ARING, M.D.
Cincinnati, Ohio

The Psychiatric Hospital Today—A Quality Profile, *by John Mulhearn and Gayle Momeny. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 138 pp., no price listed.*

Measures of quality of care tend to focus on outcome. However, Mulhearn and Momeny state that in psychiatric hospitals caring for long-term chronic illness the structure (wholesomeness of the milieu) and the process (e.g., staff concerns) are of equal importance. The data for this study of public, Veterans Administration, and private mental hospitals were obtained from 366 psychiatric hospitals that submitted questionnaires required for accreditation to the Council on Accreditation of Psychiatric Facilities. The survey data represent 181 public hospitals, 29 Veterans Administration hospitals, and 156 private hospitals and cover the period from November 1972 through November 1974. Seventeen percent of the public hospitals, none of the Veterans Administration hospitals, and 2% of the private hospitals in the study sample were nonaccredited. The authors compare the three types of hospitals on the elements that are considered essential to accreditation.

The data show that the most frequently provided services were those related to therapy. Such services as 24-hour emergency services, medical and surgical services, and pathology services were less frequently provided. The private hospitals generally provided fewer services than did public or Veterans Administration hospitals. On all variables related to the environment, with a few exceptions, private hospitals had a higher rate of compliance with accreditation standards than did public or Veterans Administration psychiatric hospitals. The authors detail the comparative findings and deficiencies in all three types of hospitals.

State hospitals were most likely and private hospitals least likely to have a psychiatrist administrator. There is some suggestion that a higher "quality" level was associated with the presence of a psychiatrist as chief executive: when that was the case, more hospitals, both public and private, had approval for two-year accreditation.

One-third of the public mental hospitals employed physicians with limited licenses to practice, but only a few private hospitals and none of the Veterans Administration facilities did.

Compliance with key safety standards was moderately high; most of the hospitals complied with all key organizational standards. The highest psychiatrist:patient ratios were in private psychiatric hospitals. However, therapeutic personnel:patient ratios were fairly comparable for all three types of hospitals.

In essence, most psychiatric hospitals were found to be better than the generally held opinion of them.

I found this thin volume packed with interesting data; I believe other administrators would agree. The data give a comprehensive overview of psychiatric hospitals as seen from the perspective of fulfillment of accreditation standards during the period 1972–1974. The book is highly recommended for administrators, trustees, and all personnel involved in the auditing process or in the evaluation of psychiatric hospitals.

WALTER E. BARTON, M.D.
Hartland, Vt.

Nightmares and Hobbyhorses: Swift, Sterne, and Augustan Ideas of Madness, *by Michael V. DePorte. San Marino, Calif., Huntington Library, 1974, 160 pp., $10.00.*

The very able British psychiatrist and historian Richard Hunter once answered the question of why the history of psychiatry has been neglected with the statement that psychiatry is only in part a medical discipline. He went on to say that philosophical, theological, social, and even literary forces have played their part in shaping it and still do.

Prof. Michael DePorte's thesis in this perceptive gloss on eighteenth-century literature is that the writings of the giant litterateurs of the Augustan era delineate Augustan concepts of mental disorders.

The times of which DePorte, a professor of English, writes comprised the age that gave rise to the notorious Bedlam, where Hogarth, among others of the 96,000 annual visitors, pictured the chaos of passions run riot. The causes of mental disorders were ascribed to an Augustan variant of Newton's widely accepted mechanistic hypothesis of the universe as a self-moving machine governed by physical laws. It followed then that purging, blistering, bleeding, cupping, and beating were the appropriate countermeasures to the "unreasonable" departure of mental disorders from physical orderliness (as the eighteenth century pictured well-being). Hobbes had earlier given credence to the priority of order in *Leviathan*, in which he said, "Without Steddinesse and Direction to some End, a great Fancy is one kind of Madnesse."

In the first 45 pages of *Nightmares and Hobbyhorses*, DePorte presents a précis of the philosophical and literary varia-

tions on the theme that epitomized abnormal psychology in England from 1660 to 1760.

The English malady, or splenism, as it was called, was thought to be the cause of "vapours, hysteric fits, the hyp and melancholy." Dr. Thomas Sydenham contended that the malady constituted fully one-half of all the chronic diseases in England. The essence of this madness was explained by Thomas Tryon. Tryon was an enlightened merchant who inveighed against not only the practice of bloodletting but also the practice of making "a Show of those Unhappy Objects of Charity by exposing them . . . to the Idle Curiosity of every vain Boy, petulant Wench, or Drunken Companion." Tryon believed that the "Soul loseth its distinguishing property . . . and becomes rampant [and] is unchain'd or set at liberty from the dark Confinements of the grosser Sense and Reason." Madness, according to the belief of the day, involved a triumph of fancy over sensation.

The second chapter of the book is titled "Swift: Madness and Satire." It is a 55-page critical essay on Dean Swift, who has been called the most misinterpreted and misunderstood man of his day. Swift—the man of wit, the disillusioned idealist and the congenital misanthropist—is illuminated in the chiaroscuro of his works. Etched by the vitriol of his satire, Swift's metaphors conceal/reveal a scathing political commentary, a mastery of irony alloyed with mordant wit, and, altogether, a skeptical analysis of human frailty.

In his third chapter DePorte devotes 30 pages to Laurence Sterne's "shandeisms," those eccentric journeys written to counteract depression caused by splenism. Of *Tristram Shandy* Sterne said, "If 'tis wrote against anything 'tis wrote, and 'please your worship, against the spleen." Sterne's intentions were consonant with the prevailing beliefs of the eighteenth century. Few men were free from the madness of falsely associated ideas; laughter and wit were "against the spleen."

It is DePorte's reading of Swift and Sterne as exemplars of the beliefs of their period that "whereas Swift has stressed the perversity of madness as a willful departure from the common forms, Sterne takes pains to show the degree to which it arises as a natural response to experience."

Both Swift and Sterne wrote out of bitter personal experience with fits of splenism. In *The English Malady* (1733) Dr. George Cheyne wrote that he "would earnestly recommend to all those afflicted with Nervous Distempers, always have some innocent entertaining Amusement to employ themselves in." This is the advice of a psychiatrist who lived to be 72 despite being a "tun of a man" who weighed 32 stone (448 pounds) and who has been called "the Aberdeen Falstaff."

In our time, when the trend in psychiatric writing grows ever more psychopharmacological, it is indeed a refreshing contrast to read an elegant literary analysis of the ideas of mental disorder that prevailed more than 200 years ago. *Nightmares and Hobbyhorses* deserves a prominent place in the accumulating studies in the history of psychiatry.

HOWARD P. ROME, M.D.
Rochester, Minn.

Hyperactive Children: Diagnosis and Management, *by Daniel J. Safer, M.D., and Richard P. Allen, Ph.D. Baltimore, Md., University Park Press, 1976, 233 pp., $8.50 (paper).*

The authors estimate that the prevalence of developmental hyperactivity in elementary schoolchildren is 5%; therefore, they state, it is the most common psychiatric disability in children. Although hard prevalence figures are difficult to establish because of the imprecision of diagnostic criteria, hyperactivity in children is a serious problem, and its management involves a substantial number of professionals from several disciplines. Hence this practical clinical guide should be of considerable help to students learning about and practitioners working with severely hyperactive children. Leon Eisenberg aptly states in the foreword, "I wish there had been something like it when I began my training."

Three central themes dominate the text: in the management of hyperactive children the school plays a vital role, multiple modes of intervention are generally more valuable than unidimensional efforts, and stimulant medication and behavior therapy are more effective than other treatment approaches. In 10 chapters the book describes the syndrome and its diagnosis, including a set of useful tests; discusses pharmacological and behavioral approaches to management, the latter both in the home and in the classroom; highlights the role of special education; and emphasizes the need for coordination among the various clinicians and teachers.

The authors are well qualified to address a diverse audience. The writing represents the combined efforts of a child psychiatrist and a clinical psychologist, both of whom have substantial experience in working with schoolchildren and schools. However, some disadvantages accrue from their attempt to produce a text equally useful to physicians, teachers, and many others. To keep the chapters uncomplicated and brief, much of the important information is placed into some 140 notes appended to the chapters. The notes are understandable when read separately, but the same information probably could have been incorporated into the text with greater brevity. There are also nearly 700 references—a desirable quality for a textbook, but somewhat overwhelming for one geared primarily for practitioners. I also found it troublesome that the authors use adjectives to describe individuals; for example, they refer to the children as "hyperactives."

The authors make a serious attempt to delineate developmental hyperactivity from such other entities as minimal brain dysfunction, specific learning disability, and brain damage. Primarily because of the current lack of knowledge, this goal is not fully accomplished. For example, the chapter on educational management addresses the problems of children with specific learning disabilities rather than those with developmental hyperactivity.

Readers seeking more in-depth or more theoretical information on this and related topics might find other books, e.g., those by Cantwell (1), Wender (2), and de la Cruz and associates (3), better resources; but those who wish to read primarily about the practical issues of management of children with developmental hyperactivity will find this text of excellent utility.

GEORGE TARJAN, M.D.
Los Angeles, Calif.

Letters, Vol. 2: 1951–1961. Bollingen Series XCV, *by C.G. Jung; selected and edited by Gerhard Adler with Aniela Jaffé; translated by R.F.C. Hull. Princeton, N.J., Princeton University Press, 1976, 638 pp., $20.00.*

From the pages of these 460 letters written by Jung between his 76th and 86th years the old scholar emerges sharp of wit, a feisty pundit, then again a wise and generous doctor to all the troubled people who wrote him. To me these letters reveal Jung's sincere human responsiveness, his endless patience at trying to explain his ideas or answer questions from anyone who would write him. He had a kind and simple way of speaking to the ordinary people who wrote him of their suicidal ideas, their homesickness, their marital problems, their dreams, their depressions, their phobias, and their demons.

He complains bitterly of his disappointment at not being understood or being misunderstood, of being misrepresented by people who had never read his works or were unable to comprehend his ambiguities and metaphorical and paradoxical statements. He resigns himself to being understood posthumously, a fate that has come true.

Those few who fought for him, who understood, who wrote favorable reviews of his books or sent him their books, offered gestures that broke through his loneliness and his sense of isolation, moving him to great appreciativeness.

There are some very long, complicated letters in this collection that bored me; although I read them all carefully I would not urge the average reader to eat all the offerings of this elegant and rich smorgasbord. Jung is trying to explain himself: he does a good job and yet how almost impossible it is to "explain" such ideas as archetypes. One of the great scholars of Western thought, Jung is just not easily understood. He abhorred popularization and stupidity. He was an intellectual who distrusted intellectuals and wrote for intellectuals. He tried to tell them of the therapeutic value of the myth, the collective unconscious, individuation, the soul, and the reality of the psyche.

Jung was convinced that mankind was at a precarious state of existence and could easily fall victim to collective man, to disastrous pollution of water and air, to radioactivity and the bomb, to overpopulation with its consequent genocide, and to noise. The din of his technology is welcome to man, he says, because it shelters him from his instinctual warnings; fear loves noise.

Many letters are answers to questions people put to him as the Wise Old Man of Küsnacht. Occasionally, however, Jung comes off as curmudgeon and, in at least one letter sent in confidence to a colleague, as indiscreet. Unfortunately, this letter was auctioned and published elsewhere before its publication here. Of course, Freud gets his share of Jung's appraisal, colored by the feelings of bitter disappointment and the lifelong pain of the broken relationship. This book has little to do with Freud, however; it has a lot to do with honesty, with man's spirit, and with what to Jung was God.

Jung clearly explains why he did not have to *believe* in God: "I know!" This statement, made during the famous BBC interview with John Freeman in 1959, impressed, surprised, and stunned many people.

Presented in chronological order, these letters show no deterioration, no loss of verve or insightfulness, an almost unquenchable curiosity, and a growing weariness in old age. Jung's commentaries on alchemy may turn off the average reader, who does not understand that Jung was interested in Eastern and medieval alchemy because it was a confirmation of the collective unconscious and revealed through its psychological, religious, and symbolic elements a bridge between Gnosticism and Christianity.

Jung does not spare us a view of his dark side, his shadow, which he willingly admits and accepts as part of his personality. He was also fully aware of his good fortune to be independent and wealthy and how this gave him a freedom denied to most others. Those who are unfavorably inclined toward Jung, those who bear secret prejudice or are looking for faults, will find them. He kept a bust of Voltaire in his waiting room at Küsnacht to remind his patients and himself that besides the amiable doctor there was an old cynic, a dubious man, a man whose ideals, morals, motives, and aspirations were all too human.

I found myself annoyed at him as he expended such energy, intellect, and affect writing letters to theologians. The time these letters were written coincides with the publication of *Answer to Job*, which brought Jung endless disappointment because it was negatively received by most theologians. Why did he expect otherwise? He held such a low estimation of most theologians, it was perhaps a case of mutual nonadmiration. I got bogged down in his long, painful, almost tormented correspondence with Father Victor White. How much he wanted to have Father White and the theologians understand his comparative psychology of religious symbolism, his idea of the God-Image, the archetype of the self.

Jung is speaking to and for the individual of treasures drawn painfully from a lifetime encounter with the unconscious. I am grateful for these human letters. It is beneath Jung that he should be deified and venerated in cultish groups or written off as an esoteric, woolly-headed mystic. He was one of the world's great psychologists, a genius who has much to say to men and women in general and psychotherapists in particular. I would strongly urge anyone who wants to know Jung to read both volumes of his letters. I would recommend them as required reading in the history of psychiatry and psychology.

HARRY A. WILMER, M.D., PH.D.
San Antonio, Tex.

Annual Progress in Child Psychiatry and Child Development 1975, *edited by Stella Chess, M.D., and Alexander Thomas, M.D. New York, N.Y., Brunner/Mazel, 1975, 541 pp., $17.50.*

The appearance of the current volume in this series makes it possible once again to breathe more easily. The imminent decline and the potential demise of quality in the field of child psychiatry predicted in the last year's review seem to have totally reversed themselves. The group of articles selected from the 1974 literature for the current volume of *Annual Progress* reminds one of the early editions of this series in the late 1960s and early 1970s.

A new heading, Social Issues and Public Policy, groups together a series of chapters in the opening pages of the volume. In these papers Judge Bazelon asks "Whose Problem" problem children are; Urie Bronfenbrenner relates public policy to the research issues involved; and Mary Mercer assembles her well-known data into an article concerned with policy on assessment procedures. Her intriguing and clear writing style makes this the outstanding contribution under the opening rubric.

There are a host of other good articles throughout the volume as well. Adelson and Fraiberg contribute another of

their moving papers on the blind child. Barbara Tizard and Rees offer an excellent description of "The Effects of Adoption, Restoration to the Natural Mother, and Continued Institutionalization on the Cognitive Development of Four-Year-Old Children." The category of Racial Issues includes Edmund Gordon's appropriately titled "An Affluent Society's Excuses for Inequality," which provides an excellent review of the relationship between school activities and intelligence.

An equally clear and definitive statement on autism by Rutter leads off the section on the psychoses. In his classic style Rutter makes vivid the host of problems associated with the diagnosis but also offers comfortable resolutions for most of them. An item of particular interest to me is an article by Eron and associates (originally published in the *American Journal of Orthopsychiatry*) with the imposing title of "How Learning Conditions in Early Childhood—Including Mass Media—Relate to Aggression in Late Adolescence." This chapter offers even more than its title suggests. Stressing the stability of aggressive behavior over a 10-year period and the changes that recent cultural alterations have produced, the authors conclude that "low identification with both parents is the most potent predictor of aggression irrespective of the subject's sex." For those concerned about developmental problems related to aggression this short paper is a gold mine of information and leads.

There are still other excellent articles. McDermott and Char's challenge in the "Undeclared War Between Child and Family Therapy" is only one of several papers suggesting that there are and will be changes in clinical practice as well as in understanding of development. Equally intriguing is Spinette's "Understanding of Death in Latency Age Children."

As noted above, faith has been restored. The child field seems healthy; the productivity is good. The aggregate in this volume is once more well worth the cost.

HENRY H. WORK, M.D.
Washington, D.C.

Latency, *by Charles Sarnoff, M.D. New York, N.Y., Jason Aronson, 1976, 394 pp., $20.00.*

Freud described the years from 5 to 12 as the latency, the part of a child's life when strong infantile sexual impulses are to some extent mastered and remain latent until they are reawakened in the physical and emotional flowering of adolescence. The repression of infantile sexuality and the control of primitive aggression is a gradual process, even a painful and reluctant one. There is also the child's shift from dependence on parents to peers, the development of moral reasoning, achievement and competence motivation, self-esteem, cooperation, and competition.

In *Latency* Dr. Sarnoff confronts this overly simplistic and actually naive description of latency and replaces it with a thorough, rational, and practical analysis of what any clinician who has worked with children in this age group recognizes as a highly active and tumultuous period. It is to the author's credit that he not only does an extremely thorough job in his analysis of this period, but that he does it with good humor. He notes,

> I myself had entered child psychiatry in the company of some who still believe firmly that latency children were quiet, and that the drives diminished in latency to almost nonexistence. What they believed, they saw, and I, wishing to find a place among them, was ready to agree and to see as they saw. My attempts to carry through this intention were short lived. The very first latency age youngster to whom I was assigned as a therapist tore the theory to shreds and cast it to the winds.

Sarnoff bases his research on extensive case histories and what is obviously a busy private practice in the treatment of children in this age group. He evolves what he defines as the structure of latency as an attempt to dissipate stress through fantasy. When the child is successful in discharging such stress he is in a state of latency. For Sarnoff, it is the potential for achieving this state that defines the years from 6 to 12. He believes that the state of latency is the result of an uneasy equilibrium between social and maturational demands effected through the establishment and organization of ego mechanisms specific for this period. He identifies these mechanisms in terms of cognitive development, sexuality, superego development, and various mechanisms of defense.

This work is an interesting mix of psychoanalytic theory and practical everyday advice for the child psychotherapist or child analyst in his or her treatment of the latency age child. Sarnoff expands his thesis into some fascinating theoretical considerations involving the ontogenesis of system consciousness, the origins of latency in prehistory, and, finally, pathological conditions in latency.

There is no doubt in my mind but that this book represents the most definitive statement on latency in psychoanalytic theory today. Certainly it can be said that it has laid to rest forever the theory that latency is a quiet period of very little clinical or developmental significance. *Latency* is highly recommended for those theoreticians and clinicians who wish to explore an imaginative if not encyclopedic analysis of the period of childhood we identify as latency.

JOHN C. DUFFY, M.D.
Bethesda, Md.

Advances in Sleep Research, Vol. 2, *edited by Elliot D. Weitzman, M.D. Holliswood, N.Y., Spectrum Publications (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1976, 231 pp., no price listed.*

This second volume in the *Advances in Sleep Research* series again underlines the breadth of the studies undertaken by sleep researchers in their multifaceted attempt to explicate our knowledge of sleep. Although this volume is less successful than the first volume, Dr. Weitzman has selected important topics by researchers deeply immersed in their area of sleep research who present effective and informative reviews.

Gardner and Grossman present an excellent essay on "Normal Motor Patterns in Sleep in Man." Following a clarifying review of methodological problems in the study of body movements during sleep, they explore the correlates and origins of large and small movements, which have been presumed to be related to rest and to dreams, respectively. They provide a particularly valuable description of the common center theory (often incorrectly called the scanning hypothesis), with additional evidence in support of a correlative relationship between limb movement and dream activity. The considerable importance of this area of work is twofold: first, as a potential basis for a theory of sleep function; and second, in the understanding of mind-body relation-

ships that it provides using dreaming sleep as a paradigm.

Sleep apnea with excessive daytime sleepiness is one of the sleep pathologies that has recently received increasing clinical attention. Orem and Dement, in their chapter on "Neurophysiological Substrates of the Changes in Respiration During Sleep," contribute to our understanding of the neurophysiological mechanisms that produce apnea during sleep. They infer from their research on single-cell recordings of respiratory neurons in cats that there are three mechanisms that produce apnea during sleep: "The first, which occurs mainly in wakefulness and non-REM sleep, is the result of continuous firing by ventrolateral medullary expiratory neurons. The second and third, appearing almost exclusively in REM sleep, are a defect in respiratory rhythmicity and a complete failure of respiratory drive."

Three other reviews are of high interest as well. The chapter by Anders on "Maturation of Sleep Patterns of the Newborn Infant," besides providing interesting data on the developmental aspect of various physiological measurements during sleep, calls attention to the importance of state-trait differences in studying sleep and to the view of development as not being a straight line but involving a series of transformations. The article by Tanaka and associates, "A Sleep Study of Acute Psychotic States Due to Alcohol and Meprobamate Addiction," resolves a discrepancy in the literature as to whether alcoholic delirium is the overflow of REM into waking. Tanaka and associates point out that much of the sleep of patients with delirium resulting from alcohol or meprobamate is made up not of classical REM but of a low-voltage, mixed-frequency EEG, REM bursts, and a tonic mental EMG. Okuma, Fukuma, and Kobayashi report on their use of a home "dream detector" that obtains dream content relatively free of laboratory influences. Their data support the view that laboratory-collected dreams may not be an appropriate sample of dreams from which to generalize.

This second volume in the series clearly contains work of great interest (chapters 1, 2, 3, 9, and 10). Unfortunately, the remainder of the articles (chapters 4, 5, 6, 7, 8, and 11) report on work of less general value or interest. These latter chapters are bound too closely to experimental data and lack the more definitive review and summary that make the essay by Gardner and Grossman so valuable.

Advances in Sleep Research, Vol. 2, is, like its predecessor, a valuable and useful summary for the researcher in sleep and the clinician who wants to keep abreast of the work in sleep.

I would express the hope that the editor of this valuable series be more selective in his choices for inclusion, provide an introduction to each volume that places the series and volume in some perspective, and, lastly, consider focusing each volume around some topic or issue in sleep research.

MILTON KRAMER, M.D.
Cincinnati, Ohio

No Single Thread: Psychological Health in Family Systems, *by Jerry M. Lewis, M.D., W. Robert Beavers, M.D., John T. Gossett, Ph.D., and Virginia Austin Phillips. New York, N.Y., Brunner/Mazel, 1976, 260 pp., $13.95.*

This is an important book for the few who have pronounced the death of the family and for the many who are fully aware of the weaknesses of the family system but see no better alternative. The literature overflows with descriptions of families that are seductive, schizophrenogenic, skewed, schizmatic, and generally shaky and sick. Lewis and his associates proclaim that there are at least a few families that are alive and well and living in middle America.

No Single Thread describes the conception, performance, and conclusions of a research study involving 44 families, 12 of which were studied intensively. All of the families were intact, the oldest child in each family was in mid-adolescence, and no family had a member in self-acknowledged psychiatric or legal difficulty. Lewis and associates acknowledge that their sample was narrow in that it was drawn from a Texas community of white, middle-class, churchgoing people. Nevertheless, their observations and conclusions appear to provide important clues about successful and healthy family functioning.

The primary goal of the project was to measure interactional data. The research framework was systems oriented rather than a study of family profiles made up of individually based, content-oriented data. The authors believe that family strengths are better understood through the study of the total family system than through the study of the family members individually, although specific problems were more readily apparent from interviews with the individuals.

In the pilot study, which investigated 23 families (12 of these contained a recently admitted adolescent inpatient and 11 were controls), a number of basic research questions were explored. These included the selection of appropriate family interactional tests, videotaping of family sessions, and the selection of both long and short excerpts from the tapes for rating. The authors also solved problems posed by the use of raters who varied widely in their levels of training and experience.

Chapter 3, titled "A Theoretical Basis for Family Evaluation," describes five family qualities considered most important in the development of optimally functioning individuals. These include the power structure, the degree of family individuation, acceptance of separation and loss, perception of reality, and affect. Each of these qualities is described as it applies to the severely disturbed family, the mid-range family (in which there is neurosis or behavior disorder), and the healthy family. I found this to be a most useful theoretical approach to the question of incompetence or competence of the family system as a vehicle for the growth and development of individuals.

The next 5 chapters describe various aspects of the research study and include comprehensive pictures of the 12 most intensively studied families in fascinating detail. Descriptions of the research instruments used are also provided in these chapters.

The final 2 chapters, which include an overview of the study and the implications of the findings for the clinician, contain a wealth of important observations. These generally stress that the optimally functioning families apparently derived their strength from the presence and interrelationship of many variables, there being no single formula for family health. Caring, basic trust, respect for varying perceptions of the world, willingness to explore different avenues to the solution of problems, a high degree of personal autonomy, openness to expression of feeling, and an ability to see themselves as others see them are among the most significant of these variables.

The importance of this book is that it should stimulate the reader to consider the possibility of teaching families some of the qualities that may lead to the successful growth, development, and "death" of the total family unit after it has served its primary purpose. It is probably too late to teach

much of this material to severely disturbed or mid-range families, but it would be revolutionary if we were able to introduce courses for living into the schools that would counterbalance the stress on acquisition of affluence as the primary goal of education by teaching about issues that might lead to lives with emotional strength and quality. For mental health professionals, teachers, and others, this book is worth studying.

N. MICHAEL MURPHY, M.D.
Albany, N.Y.

Brain, Behaviour and Drugs: Introduction to the Neurochemistry of Behaviour, *by David M. Warburton. New York, N.Y., John Wiley & Sons, 1975, 252 pp., $18.50.*

This volume provides a short introduction to several areas of neurochemistry and neuropharmacology that are relevant to important behavioral phenomena. The book is written in the easy style of British textbooks and can be read through without much difficulty. This quality results in part from the fact that a great deal of effort has gone into integrating the material in each chapter. The author does not make excessive use of subtitles and, although the book is adequately referenced, the references are limited to those which are essential. This makes the volume somewhat less useful as a reference book but enhances its value as a textbook.

The book consists of sections on the chemical nature of synaptic transmission, on homeostasis, mood, attention, motor control, sleep and dreams, and on biochemical aspects of the important psychiatric syndromes. A chapter on biochemical aspects of intelligence is interesting and useful in that biochemical material is not usually integrated under that rubric. There is also a very topical chapter on drug dependence.

One minor shortcoming of this book is that the use of such phrases as "biochemical basis of mood" might convey to students the impression that mood can be entirely explained in terms of biochemistry. The author reinforces this idea in his preface, in which he says there is a "trend in psychopharmacology in which attempts are being made to understand behaviour in terms of the basic neurochemical systems in the brain." A more contemporary view would hold that behavior can be influenced or modulated and even modified by biochemical manipulations but is not fully explainable in terms of any biological system. Perhaps the terminology is unintentional and the author is using "basis" to mean "aspect," in which case the ambiguity is unfortunate.

On balance, the volume is excellent. It is lucid, informative, and written in an eminently readable literary style. It should serve as a very useful book for students of psychiatry, physiological psychology, introductory neurobiology, and introductory neuropharmacology.

ARNOLD J. FRIEDHOFF, M.D.
New York, N.Y.

The Growing Edge of Gestalt Therapy, *edited by Edward W.L. Smith, Ph.D. New York, N.Y., Brunner/Mazel, 1976, 234 pp., $12.95.*

A smorgasbord can be an exciting adventure in eating, but the hope inspired often exceeds the satisfaction obtained. Something is lost in the coherence of the experience because the very variety that excites the eye sometimes confuses the palate. Smorgasbord anthologies on psychotherapy have become a popular book form. They provide many exciting and interesting moments but usually leave the reader less than entirely satisfied. *The Growing Edge of Gestalt Therapy* is in this genre and, as such, is like several books on Gestalt therapy published in the past couple of years. This one is better than most because it provides somewhat more order and cohesiveness. Nevertheless, it, too, suffers from the inherent unevenness of an anthology, with some memorable chapters and some that are not so memorable.

There are six parts to this book. The first is on the historical background of the therapy and has only a single chapter. The second, Further Explications of Gestalt Therapy, is a collection of 5 articles that have little in common with one another, viewing Gestalt therapy from different perspectives. The third, Gestalt Therapy and Jungian Psychology, contains 2 chapters. The fourth, titled Gestalt Therapy Integrated with Other Techniques and Systems, contains 4 offerings on such varied topics as hypnosis, existential therapy, a group-dynamic approach, and the use of a communication perspective. The fifth part of the book is composed of 3 chapters on Gestalt therapy and Eastern philosophy. The sixth and final part, A Summing Up, is a single short paper by Laura Perls, the widow of Fritz Perls and cofounder of the Gestalt method.

The book contains much interesting and useful information; the familiar themes of Gestalt therapy serve to bring the information together: i.e., the emphasis on the here and now, the recognition of polar opposites and the process of resolving them, integration and person-centeredness, and an emphasis on awareness, growth, and self-actualization. These and related concepts provide an increasingly recognized and accepted definition of mental health and the qualities of a fully functioning person. They are beginning to replace some of the vagaries of the "genital character" and maturity. Perhaps more important is that Gestalt therapy offers treatment approaches directed specifically toward the achievement of these qualities. As such, there is a concrete relationship between the goal of health and the methods employed. Not everyone will accept these definitions of health, but if one does the techniques are available.

The first chapter, by Edward W.L. Smith, is titled "The Roots of Gestalt Therapy" and provides the most extensive and detailed explication of the theoretical basis of Gestalt therapy yet available. It contains sections on what Gestalt therapy has derived from psychoanalysis, Reichian theory, character analysis, existentialism, Gestalt psychology, and Eastern religions. Each section is scholarly, well documented, and detailed.

A brief 4-page chapter by Robert A. Hall titled "A Schema of the Gestalt Concept of the Organismic Flow and Its Disturbance" is a succinct and valuable contribution illustrating phasic homeostasis according to the Gestalt conception. Despite its brevity, this chapter has important practical implications. An excellent diagram compares healthy and pathological perspectives.

Another especially valuable chapter, by George B. Greaves, is titled "Gestalt Therapy, Tantric Buddhism and the Way of Zen." It is both scholarly and practical, comparing Gestalt therapy and these Eastern religious approaches. Described first are the methods common to each, such as focusing and role playing. Greaves then introduces the use of the koan, the statement or question that seems to defy all laws of logic and requires fresh solution; zazen, the process of intense concentration emptying one's mind; and

mondo, the conversations between a master and student (not unlike more conventional dialogues between therapist and patient). He also discusses the use of meditation techniques to enhance psychotherapy, employing the three primary aids in the Tantric method: mantras, or sounds; mandalas, or visual designs; and mudras, or symbolic hand and finger gestures. This chapter is one of the few using the method of presentation that has become the hallmark of writing on Gestalt therapy, the recorded dialogue between patient and therapist.

Laura Perls's paper, "Comments on the New Direction," is a refreshing departure from the heavily conceptual and annotated chapters that precede it. Once again she expresses what she sees as important in Gestalt therapy: the actual experience, the awareness continuum, the relationships of time, and contact and support. She emphasizes the flexibility and personal style of the therapist to achieve these ends and evidences her commitment to the artistic elements in psychotherapy.

This book is different from its predecessors in Gestalt therapy in that it emphasizes theories and concepts rather than practice and there are very few of the usual dialogues for the reader to follow. Despite this emphasis on the conceptual, the book remains true to the effort of Gestalt therapists to achieve integration; each chapter attempts to integrate Gestalt therapy with other methods to which contributors have a commitment. In that sense, each chapter serves as a model for each therapist to find ways of putting together unique influences in his or her life beyond any single ideology.

I cannot help but feel a little wistful about the progress which this volume undeniably makes in the literature on Gestalt therapy. Although it achieves new and more sophisticated theoretical perspectives, this very sophistication detracts from the "beyond mere words" power of the method. The addition of this heavy layer of theory tends to detract from the essential experiential and concrete quality of the therapy that has caused it to grow so rapidly and to stand out among other forms.

ARNOLD R. BEISSER, M.D.
Los Angeles, Calif.

Contemporary Marriage: Structure, Dynamics, and Therapy, *edited by Henry Grunebaum, M.D., and Jacob Christ, M.D. Boston, Mass., Little, Brown and Co., 1976, 485 pp., $17.50; $12.50 (paper).*

Considering the plethora of books on marriage, Drs. Grunebaum and Christ have produced a most valuable book. It is rare to find 25 authors who vary in competence and lucidity from excellent to outstanding to scholarly. This book will become *must* reading not only for psychiatrists but for all members of the mental health professions. It is well organized and easy to read, the price is right, and the editing is superb (I found only one mistake: on page 370, reference 7 should be Lederer instead of Leder).

The contributing authors represent a spectrum of professionals: an anthropologist, a historian, a social worker, two family therapists, two lawyers, two sociologists, nine physicians, and nine psychologists. As the editors, both of whom are psychiatrists, succinctly state in their preface, "Our experiences as clinicians and teachers have convinced us that what the therapist most requires . . . is an understanding of the basic forces that impinge on and determine the course and quality of married life."

The book is divided into three sections, described by the editors as follows:

> The first discusses the social forces that impinge on marriage; the second describes the course and psychology of the marital relationship [applicable to all relationships]; and the third deals with the diagnosis [including valuable comments on prevention] and treatment of couples with marital difficulties.

In the last section a range of therapeutic approaches is offered in a sequence of excellent chapters.

In the opening chapter the editors present the myths and realities confronting marriage. They point out the importance of content vis-à-vis relationship. Their opening sentences answer the question repeatedly asked about the future of the marital institution:

> Changes in social values and obvious vicissitudes in marriage notwithstanding, the institution of marriage is still very much with us. This is true despite the fact that in many modern societies, and increasingly in our own, the satisfaction of sexual needs often takes place without the sanction of a marriage ceremony. . . . It is not the act of marrying that is changing, but rather the reasons individuals have for marrying and how they define a good marriage.

Thus in the following 2 chapters Demos (a historian) and Abernethy (an anthropologist) cogently and superbly present an important trend in marriage—the increasing importance of emotions and the decreasing value of economic forces. In another chapter the Rapoports deal with the changing transactions between work and marriage in their usual scholarly manner. This chapter should be read and reread by all therapists. The Rapoports accomplish their aim in this paper: to provide "a perspective on some salient patterns now emerging and to discuss their implications, particularly for those in the mental health professions."

Because of space limitations I cannot do full justice to the valuable materials presented in the second and third sections of this book. To do an adequate review would result in a small monograph. The book holds one's attention and contains a wealth of information. This contribution to the literature will be an often-consulted addition to the psychiatrist's library.

BERNARD L. GREENE, M.D.
Palm Springs, Calif.

Psychiatric Illness: Diagnosis, Management and Treatment for General Practitioners and Students, 2nd ed., *by H. Merskey, M.A., D.M., and W. Lawton Tonge, M.D. London, England, Baillière Tindall (Baltimore, Md., Williams & Wilkins Co., exclusive U.S. agents), 1974, 284 pp., $11.50 (paper).*

The intent of the authors of this interesting psychiatric text is generally fulfilled. Particularly well met is their effort to convey to the nonpsychiatric physician basic skills concerning the treatment of psychosexual problems in marriage and the emotional overlay that frequently compounds physical illness. Their candor in reassuring enlightened primary care physicians that they can, in fact, handle many of their patients' emotional needs is also well suited to the patients' needs.

Although I am not familiar with the first edition of this book, it was apparently well received. In reviewing this edition I found that, although well presented, the material does not seem to be well footnoted or to reflect a good cross section of *current* psychiatric thinking. In other words, the volume has apparently not been fully updated, as is at least implied in its opening chapters. In particular, it would appear that some types of emotional illnesses seen in general practice are dealt with in depth, whereas other psychiatric or psychophysiological disorders are only lightly touched on. Thus there is some lack of balance in parts of the book. For example, the issues of the dying patient and suicide are not treated fairly enough, in my opinion, to leave the average generalist with a feeling of comfort in handling patients in these situations. The generalist would most likely read Merskey and Tonge's work and then call for an emergency psychiatric consultation.

With the above exceptions, I feel that this book does meet many of the needs of the nonpsychiatric physician; I would recommend it to him or her as part of the medical armamentarium, especially in efforts to treat patients in their physical and emotional entirety. Readers on both sides of the Atlantic will find this text well worth their investment of time and money.

DONALD E. FISCHER, M.D.
Omaha, Neb.

The Therapist's Handbook: Treatment Methods of Mental Disorders, *edited by Benjamin B. Wolman, Ph.D. New York, N.Y., Van Nostrand Reinhold Co. (Litton Educational Publishing), 1976, 519 pp., $22.50.*

In providing information about psychiatric treatment to a variety of professionals, this collection covers a wide range of topics quite thoroughly in a practical way that everyone will find useful. None of the 28 authors, except the editor, contributes more than one chapter. In the first section various types of therapy are described; in the second, mental disorders are taken up one by one along with their specific treatments.

This organization, although it guarantees a methodical crisscrossing of the subject, leads to considerable unevenness, inconsistency, and, as the editor admits, "some degree of overlapping and repetition." For example, in the first section of the book Abrams creditably describes mechanisms, dosages, and side effects in psychopharmacology and convulsive therapy; in the second section some of the same points are covered again—some better, some worse—in chapters on geriatrics, depression, and schizophrenia. The inconsistency is manifested not so much in conflicts between theoretical approaches as in conflicts between the presence of several rather inflated chapters in the first section (e.g., psychoanalytic technique, hospital care, and aftercare) and the relative absence of discussion of these methods when one comes to particular disorders in the second section.

More distressing is the unevenness of depth, breadth, and quality. One author discusses a number of medications with exact milligram doses but refers the reader elsewhere for details of psychotherapy; Chessick's chapter on neuroses describes minutiae of psychotherapy but nothing about behavior therapy; Chafetz gives over 7 pages to deal with the treatment of alcoholism, but the subject of psychosomatic disorders is given 63 pages. Are psychosomatic disorders really 9 times more prevalent than alcoholism?

However, Dr. Wolman has intelligently presented a variety of approaches in a way that reflects the present state of psychiatry in transition. To try to cover everything in one book and present it for every kind of professional reader requires judicious vision. In a foreword, Bertram Brown makes the startling statement that there are more than 130 kinds of psychosocial therapy. Dr. Wolman has collected a good representation of this plenitude.

Another feature of our times evident in this book is modesty—of goals, claims for success, and advocacy of techniques—with a kindly regard for those who represent other schools and techniques. These attempts to reach out toward other disciplines may betoken the long-awaited integration of our specialty.

One final indispensable aspect for a handbook that professes to be helpful is currency. Up-to-date recognition of new boundaries appears throughout this volume, notably in chapters on drug addiction, psychosomatic disease, and modified psychoanalytic techniques. Especially first-rate in every way, particularly for their appreciation of the past and for their description of innovative methods that appear to be balanced with sound judgment, are the chapters by Lazarus on behavior therapy, Rosenbaum on group therapy, and Chessick on psychotherapy. At least for a few years, or until the next psychiatric revolution, the practitioner mainly interested in developing specificity in therapy will want this book.

C.E. SCHORER, M.D.
Detroit, Mich.

Assessment of Organic Intellectual Impairment, *by John McFie. New York, N.Y., Academic Press (Harcourt Brace Jovanovich), 1975, 161 pp., $12.00.*

This slim volume addresses the topic of neuropsychiatry. Clinical psychology has traditionally been aligned with psychiatry and considerably influenced by holistic views of brain function, exemplified by Lashley's concept of mass action (1). Neuropsychology evolved as growing evidence indicated that strong structure-function coupling existed in the cerebral hemispheres. Neuropsychology thus has as one of its objectives the development of behavioral tests for the recognition of localized cerebral lesions.

The author of this book bases his exposition on the use of the Wechsler Adult Intelligence Scale alone. This has the advantage of using a test familiar to psychologists but the disadvantages that the subtests that make up the scale were not designed to tap specific neural functions and the concept of intelligence itself is too much dominated by holistic concepts.

The volume opens with an overly brief chapter on "Neuropsychological Correlations" followed by chapters on "Testing" and "Diagnostic Interpretation." A subsequent chapter contains illustrative case studies. A separate chapter addresses itself to organic impairment in children.

Old concepts die hard, particularly if they have attained the dignity of such a name as "intellect." Thus McFie rightly rejects the concept of a single test for "brain damage" in his concluding chapter (p. 145). However, earlier, in discussing testing, he indicates that the examiner "will have been able to estimate to what extent the patient's disabilities are at the intellectual level or are at the *lower level* of disorders of language" (p. 16; my italics). What function of functions does McFie subsume under the term "intellectual," and how is this level "higher" than language? Inconsistencies such as

this, overly simplified views of cognitive and linguistic functions, and narrowly restrictive concentration on a single psychometric test constitute, in my view, the major weaknesses of this book. For neurologists and psychiatrists who wish to learn more about neuropsychological testing it is too parochial and suffers in comparison with existing monographs on this subject.

DAVID D. DALY, M.D., PH.D.
Dallas, Tex.

Progress in Behaviour Therapy, *edited by J.C. Brengelmann, J.T. Quinn, P.J. Graham, J.J.M. Harbison, and H. McAllister. New York, N.Y., Springer-Verlag, 1975, 307 pp., $31.00.*

This volume contains 36 papers that were read at a conference on behavior engineering and therapy held in Wexford, Ireland, and attended by 320 delegates from Europe and North America. These highly technical papers indicate that behavioral therapy has developed from the early learning principles to a more complex discipline based on detailed studies of both animal and human behavior. There is an increasing integration of therapies derived from experimental procedures with clinical skills and even with traditional psychotherapy. In some cases treatment of symptoms and behavior modification are combined with insight therapy.

Among the many subjects discussed are operant conditioning, behavior modification, response prevention modeling, flooding, assertiveness training, implosive therapy, aversion therapy, desensitization, self-control training, feedback techniques, and mathematical evaluation criteria. Among the disorders treated were head-banging, self-mutilation, language acquisition, agoraphobia (with the concomitant use of a beta-blocking agent), bereavement, sexual dysfunction, frigidity, speech anxiety, smoking, obesity, phobias, and even schizophrenia.

The impression gained from reading this book is that traditional analytically oriented insight psychotherapy and behavior modification therapy have much in common and much to contribute to each other. The effectiveness of psychotherapy is enhanced by the open-mindedness of the various disciplines to each other and a melding of all into a pragmatic global approach to behavior disorders. I was especially impressed by the honesty of these behaviorists in reporting failures as well as successes and their ability to improve their techniques on the basis of unbiased long-term follow-up evaluations of treatment results.

Drugs in Combination with Other Therapies, *edited by Milton Greenblatt, M.D. New York, N.Y., Grune & Stratton (Harcourt Brace Jovanovich), 1975, 188 pp., $14.00.*

In the preface of this small volume the editor indicates that "we have come to the point of asking how drugs alone compare with drugs in combination with other therapies . . . family therapy, social therapy, work therapies, and many other types of rehabilitative activity." The assignment is obviously too large to be accomplished in one small book.

There are 11 chapters of considerably variable quality. Several chapters seem not to consider the use of psychotropic drugs at all (i.e., "Drugs and Other Therapies for the Rehabilitation of the Chronic Addict"; "Drugs in Combination with Other Therapies for Alcoholics"; and "Combination of Drugs with Behavior Therapy"). The chapter on behavior therapy mentions drugs only in passing but berates psychiatrists for neglecting this treatment modality, which the authors do little to clarify.

The chapters on "Drugs and Sociotherapy in the Aftercare of Schizophrenia" by Hogarty, Goldberg, and Schooler; on "Drugs and Rehabilitation in Schizophrenia" by Chien; on "Long-Acting Phenothiazine and Social Therapy in the Community Treatment of Acute Schizophrenia" by Goldstein, Rodnick, Evans, and May; and on "Psychotherapy and Drugs in Schizophrenia" by Grinspoon and Shader address themselves to the issue of drugs in combination with other therapies by reporting work in progress and considering the many problems faced in complex studies. For the most part, the studies reported would not guide the seasoned clinician in his or her everyday work, but they would help induce a proper sense of humility in his or her approach to the tougher patients. The chapter on "Psychotropic Drug Combinations: Good and Bad" by Ayd is instructive and enlightening, but the other therapies in this chapter are just other drugs.

An important and perhaps the most useful feature of this book is the inclusion of a fairly extensive bibliography after each chapter.

I believe that some usefulness can be extracted from some parts of this volume, but the time spent reading it would be more rewarding if spent reading other sources of similar information, often from the same authors.

DOUGLAS GOLDMAN, M.D.
Cincinnati, Ohio

The Varieties of Abnormality: A Phenomenological Analysis, *by Raymond J. McCall, Ph.D. Springfield, Ill., Charles C Thomas, 1975, 560 pp., $22.50; $16.69 (paper).*

Stating flatly that we have no knowledge of etiology on which to base a rational therapy and only a nominal agreement on classificatory criteria, McCall rejects any discussion of etiology or treatment methods as mere speculation and elects to apply an approach that he calls "phenomenologically oriented clinical description." It is not a classical experiential phenomenology but, rather, a descriptive behavioral phenomenology based on the author's observations or the reported behavioral observations of others (one is never sure which furnishes McCall's basic data). His method, then, might properly be called rational and authoritative rather than phenomenological.

The result is a curiously nostalgic book that reads like the classical texts of the prepsychoanalytic, pre-experimental psychopathology days of psychiatry. It is replete with long and detailed case histories, but one misses any reference to the modern contributions of genetics, psychopharmacology, or behavior modification.

McCall's opening chapter defines normality as the psychological conditions favorable to the individual's attaining the good life. Abnormality is the opposite. His next chapter deals with the classic defense mechanisms; he sees these as

ineffective and helping to "set the stage for neurotic and other maladaptive symptoms." McCall denies that neurosis is an autonomous disorder and claims that the various neurotic behaviors are symptom complexes found as part and parcel of schizophrenia, depression, character disorder, situational stress reactions, and every other kind of personality aberration but not existing independently as disorders in their own right.

There follows a discussion of the "functional" psychoses, those not known to possess an organic etiology. The treatment here is strictly classical and includes the simple, hebephrenic, catatonic, and paranoid subtypes of schizophrenia. McCall then includes a chapter on personality disorders, which he considers of pathological significance but widely neglected in the literature. These are classed as inadequate, schizoid, paranoid, cyclothymic, compulsive, and hysteroid. In a way reminiscent of Kretschmer these disorders are related to the more serious psychotic behaviors.

The section on character disorders that follows is the longest in the book (some 200 pages) and includes sociopathy, alcoholism, drug abuse, and sexual deviation (homosexuality is viewed as grim, not gay). The lack of etiological data and classificatory agreement in these areas lends encouragement to McCall's descriptive approach. There is in his treatment a sometimes overt, sometimes latent, moralizing that, although refreshing, runs counter to humanitarian attitudes typical in the field.

The book closes with a discussion of "Disorders of Presumably Known Etiology," which covers the organic disorders (including a 5-page treatment of "neurodermatitis also called atopic dermatitis"). Here the author exhibits his fascination with medical terminology and symptomatology, a tendency present throughout the volume that contributes to its nostalgic aura. There is a glossary, an index, and a bibliography, over 90% of which is pre-1970.

McCall writes well, if somewhat petulantly at times, and there are many interesting ideas embedded in the book. It should make pleasant reading for students, but I doubt its acceptance by many of their professors.

WILLIAM A. HUNT, PH.D.

The Biofeedback Syllabus: A Handbook for the Psychophysiologic Study of Biofeedback, *edited by Barbara E. Brown, Ph.D. Springfield, Ill., Charles C Thomas, 1975, 495 pp., $26.50; $19.75 (paper).*

The Biofeedback Syllabus: A Handbook for the Psychophysiologic Study of Biofeedback is misnamed. A more appropriate title for this annotated bibliography would be *Psychophysiology Syllabus: A Limited Bibliography*. The work contains more than 1,400 references to articles pertaining to the psychophysiology of electrodermal activity, blood pressure, heart rate, muscle activity, and EEG, plus a smattering of references to studies of other body systems. Each reference is followed by an abstract summarizing the basic points of the paper. The syllabus is organized by sections on body systems under which appear various subheadings. References are usually included on measurement, instrumentation, control mechanisms, correlates of behavioral and cognitive states, and psychopathology; lists of review articles are given under a separate heading.

Poor organization is this book's most limiting factor. Headings are not followed consistently from system to system. A separate heading for clinical studies within each section would have been useful but is not included. Each section is followed by an index of descriptor terms with a key to articles containing relevant information. However, the lack of any master index for the entire book makes it difficult for the student to identify response systems relevant to a particular issue. Articles published before 1965 are listed in an appendix to each section; papers that should be given much more prominence in a basic reference source are thus hard to find. Articles on operant control of autonomic responses are listed separately from those on biofeedback. These inconsistencies in organization are confusing to both novice and expert readers.

Examining the contents of this book one wonders why the work was called *The Biofeedback Syllabus*. The editor states her reason: "Because of the limitations and control inadequacies of the scientific method as applied to organisms capable of discriminating the significance of elements in their environment, *there can be no sharp dividing line between biofeedback and other learning processes*." This is a strong statement and one that needs considerable support if it is to be used as the framework of a reference book. For instance, why are studies of classical conditioning included here? Classical conditioning is not biofeedback, no matter who the experimental subject is, because the stimulus is not contingent on the response. Nor is the relationship of electrodermal activity or heart rate to psychopathology necessarily relevant to biofeedback. The impression given in this book is that biofeedback *is* psychophysiology. This idiosyncratic definition of the field makes this collection of references neither a bibliography of biofeedback nor one of psychophysiology. To be truly useful, a bibliography must be totally exhaustive or narrowly circumscribed. This one is neither and is therefore of limited value.

Adolescent Psychiatry, Vol. IV: Developmental and Clinical Studies, *edited by Sherman C. Feinstein and Peter L. Giovacchini. New York, N.Y., Jason Aronson, 1975, 410 pp., $20.00.*

Many years ago, when the Menninger Foundation was still the Menninger Clinic and I was still a psychiatric aide there, a young Topeka psychiatrist named Bernard Hall was talking with me about adolescents and adolescence (a time of life I was then experiencing myself). He said that psychoanalytic theory was developing significantly its efforts to comprehend adult behavior and early childhood personality. But, he added with exasperation, when it came to the age of adolescence, "all hell breaks loose," for both the person and the theory.

This fourth volume of *Adolescent Psychiatry* is an important contribution toward clarifying some of the huge hunks, bits, and pieces of that dual explosion. A distinguished group of contributors, well chosen by Feinstein and Giovacchini, direct their efforts toward behavior, personality process, and developmental issues as well as toward psychopathological development. There is also a series of chapters on broader cultural issues and political and theoretical considerations. Focusing on two parallel concerns, "one dealing with the tragedies within our culture and the other with individual misery," this volume represents a significant potpourri of articles whose diversity of topics and focuses on adolescence

is comprehensive, stimulating, and infrequently flawed by disruptive variations in quality of writing and style.

With very few exceptions, each chapter has a brief summary conclusion and supporting references. The overall collection has a single index. To blend the various sections together the editors have woven in transitional comments.

I sensed an unwritten, cautious, perhaps unintended attitude of optimism in the book as a whole, an optimism that perhaps we are about to begin to understand some of the important interactions of adolescent behavior, parental attitudes, and cultural style as they influence each other. Fritz Redl echoes, decades later, Bernard Hall's exasperated, accurate accounting of the psycho-physiological-spiritual state known as adolescence: "We can only reassure ourselves by being realistic and acknowledging that in our equations there are more unknowns than knowns." Redl's brief snapshot of the adolescent's emigration and immigration reminds us of Bernfeld's earlier (1938) observation on three common developmental styles of adolescence, which, when placed in focus with contemporary knowledge of sociocultural styles of parenting, blossom into an understanding of frequently observed family dissonances that enter our 1976 consultation rooms regularly. As such, some significant pieces of the "hell broken loose" begin to fit and make sense, a sense that is practical in that it can be translated into treatment designs for bringing family understanding to the bewildered parents and teenagers staring at each other across the ever-present generation chasm so exaggerated by our culture's precariously hyperkinetic pace.

In summary, I recommend this volume of *Adolescent Psychiatry* to all readers interested in adolescent behavior as an important collection of theoretically thoughtful, useful, and provocative articles on contemporary adolescence in Western culture.

RICHARD E. DAVIS, M.D.

This Month's Reviewers

JUDD MARMOR, M.D., is Franz Alexander Professor of Psychiatry, University of Southern California School of Medicine, Los Angeles, Calif.

CHARLES D. ARING, M.D., is Professor Emeritus of Neurology, University of Cincinnati College of Medicine, Cincinnati, Ohio.

WALTER E. BARTON, M.D., is Senior Physician, Veterans Administration Hospital, White River Junction, Vt., and Professor Emeritus of Psychiatry, Dartmouth Medical School, Hanover, N.H.

HOWARD P. ROME, M.D., is Senior Consultant and Professor of Psychiatry, Mayo Clinic and Mayo Graduate School of Medicine, Rochester, Minn.

GEORGE TARJAN, M.D., is Professor of Psychiatry, University of California, Los Angeles, School of Medicine, Los Angeles, Calif.

HARRY A. WILMER, M.D., PH.D., is Professor of Psychiatry, University of Texas Health Science Center at San Antonio, Tex.

HENRY H. WORK, M.D., is Deputy Medical Director for Professional Affairs, American Psychiatric Association, Washington, D.C.

JOHN C. DUFFY, M.D., is Professor of Psychiatry, Uniformed Services University of the Health Sciences School of Medicine, Bethesda, Md.

MILTON KRAMER, M.D., is Co-Director, Sleep Laboratory, Veterans Administration Hospital, and Professor of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio.

N. MICHAEL MURPHY, M.D., is Deputy Director, Clinical, Capital District Psychiatric Center, and Associate Professor, Department of Psychiatry, Albany Medical College, Albany, N.Y.

ARNOLD J. FRIEDHOFF, M.D., is Professor, Department of Psychiatry, and Director, Millhauser Laboratories, New York University School of Medicine, New York, N.Y.

ARNOLD R. BEISSER, M.D., is Director, Health Training Center, and Clinical Professor of Psychiatry, University of California, Los Angeles, School of Medicine, Los Angeles, Calif.

BERNARD L. GREENE, M.D., is Emeritus Clinical Professor of Psychiatry, Abraham Lincoln School of Medicine Medical Center, University of Illinois, Chicago, Ill.; he is in private practice in Palm Springs, Calif.

DONALD E. FISCHER, M.D., is Chief of Psychiatry and Director, Douglas County Hospital Community Mental Health Center, and Assistant Professor of Psychiatry and Behavioral Sciences, Creighton University School of Medicine, Omaha, Neb.

C.E. SCHORER, M.D., is Director of Training, Lafayette Clinic, Detroit, Mich.

DAVID D. DALY, M.D., PH.D., is Professor of Neurology, University of Texas Health Science Center at Dallas, and Professor of Communication Disorders, University of Texas at Dallas, Tex.

FREDERICK LEMERE, M.D., is Clinical Professor of Psychiatry, University of Washington School of Medicine, Seattle, Wash.

DOUGLAS GOLDMAN, M.D., is Assistant Clinical Professor of Psychiatry, University of Cincinnati College of Medicine, Cincinnati, Ohio.

WILLIAM A. HUNT, PH.D., is Professor Emeritus of Psychology, Loyola University of Chicago, Ill.

RICHARD S. SURWIT, PH.D., is Director, Psychophysiology Laboratory, Massachusetts Mental Health Center, Harvard Medical School, Boston, Mass.

RICHARD E. DAVIS, M.D., is Professor of Child Psychiatry, University of North Dakota, Grand Forks, N.D.

Books Received

This listing acknowledges the receipt of recent books. Books of particular interest to the readers of this journal will be reviewed as space permits, and copies of the reviews will be sent to the publishers. Books cannot be returned to the publishers.

The Child Care Worker: Concepts, Tasks and Relationships, *by Jack Adler, Ed.D., A.C.S.W. New York, N.Y., Brunner/Mazel, 1976, 189 pp., $10.00.*

Hospitals, Paternalism, and the Role of the Nurse, *by Jo Ann Ashley. New York, N.Y., Teachers College Press, 1976, 153 pp., $9.95.*

Human Ecology and Cognitive Style: Comparative Studies in Cultural and Psychological Adaptation, *by John W. Berry. New York, N.Y., Sage Publications (Halsted Press, John Wiley & Sons, distributor), 1976, 242 pp., no price listed.*

Sexual Adventures in Marriage, *by Rüdiger Boschmann and Günther Hunold. New York, N.Y., Pent-R Books, 1976, 159 pp., $12.95.*

Psychoanalytic Technique and Psychic Conflict, *by Charles Brenner, M.D. New York, N.Y., International Universities Press, 1976, 214 pp., no price listed.*

Rating Scales, *by Enzo Codignola and Giovanna Mantovani. Milan, Italy, Essex (Italia), 1975, 208 pp., no price listed.*

Anxiety and Depression: The Adaptive Emotions, *by Charles G. Costello. Montreal, Que., Canada, McGill-Queen's University Press, 1976, 144 pp., $10.00.*

Human Diversity: Its Causes and Social Significance, *edited by Bernard D. Davis and Patricia Flaherty. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 241 pp., no price listed.*

The History of Psychotherapy: From Healing Magic to Encounter, *edited by Jan Ehrenwald, M.D. New York, N.Y., Jason Aronson, 1976, 583 pp., $25.00.*

The New Volunteerism: A Community Connection, *by Barbara Feinstein and Catherine Cavanaugh. Cambridge, Mass., Schenkman Publishing Co., 1976, 178 pp., $11.25.*

Theoretical and Experimental Bases of the Behaviour Therapies, *edited by M. Philip Feldman and Anne Broadhurst. New York, N.Y., John Wiley & Sons, 1976, 434 pp., $26.00.*

The New Games Book, *edited by Andrew Fluegelman, New Games Foundation. San Francisco, Calif., Headland Press (Garden City, N.Y., Dolphin Books, Doubleday & Co., distributor), 1976, 191 pp., $4.95 (paper).*

Child Behavior Analysis and Therapy, *by Donna M. Gelfand and Donald P. Hartmann. New York, N.Y., Pergamon Press, 1975, 321 pp., no price listed (paper).*

Cannabis and Health, *edited by J.D.P. Graham. London, England, Academic Press (Harcourt Brace Jovanovich), 1976, 447 pp., £14.50.*

Biomedical Ethics and the Law, *edited by James M. Humber and Robert F. Almeder. New York, N.Y., Plenum Press, 1976, 538 pp., $19.50.*

Piaget and His School: A Reader in Developmental Psychology, *edited by Bärbel Inhelder and Harold H. Chipman; Charles Zwingmann, coordinating editor. New York, N.Y., Springer-Verlag, 1976, 288 pp., $14.80 (paper).*

Maturation of the Therapeutic Community: An Organic Approach to Health and Mental Health, *by Maxwell Jones, M.D. New York, N.Y., Human Sciences Press (Behavioral Publications), 1976, 163 pp., no price listed.*

The Powerholders, *by David Kipnis. Chicago, Ill., University of Chicago Press, 1976, 227 pp., $12.50.*

From Group Dynamics to Group Psychoanalysis: Therapeutic Applications of Group Dynamic Understanding, *edited by Morton Kissen. Washington, D.C., Hemisphere Publishing Corp. (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1976, 352 pp., $21.95.*

Basic Visual Processes and Learning Disability, *by Gerald Leisman. Springfield, Ill., Charles C Thomas, 1976, 407 pp., $27.50.*

Physiologic Disposition of Drugs of Abuse, *by Louis Lemberger, M.D., Ph.D., and Alan Rubin, Ph.D. Holliswood, N.Y., Spectrum Publications (New York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1976, 390 pp., no price listed.*

The Dynamics of Human Service Delivery, *by Gilbert Levin and Edward B. Roberts, with Gary B. Hirsch, Deborah S. Kligler, Jack F. Wilder, and Nancy Roberts. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 257 pp., $16.00.*

Sex Education in Medicine, *edited by Harold I. Lief and Arno Karlen. Holliswood, N.Y., Spectrum Publications (New*

York, N.Y., Halsted Press, John Wiley & Sons, distributor), 1976, 151 pp., no price listed.

Film and Suspense, *by Altan Löker. Istanbul, Turkey, Altan Löker, 1976, 231 pp., $400 (paper).*

Scientist As Subject: The Psychological Imperative, *by Michael J. Mahoney. Cambridge, Mass., Ballinger Publishing Co. (J.B. Lippincott Co.), 1976, 242 pp., no price listed.*

The Achievement Motive, *by David C. McClelland, John W. Atkinson, Russell A. Clark, and Edgar L. Lowell. New York, N.Y., Irvington Publishers (Halsted Press, John Wiley & Sons, distributor), 1976, 384 pp., no price listed.*

ANNUAL INDEX

Following is the comprehensive index for volume 133 of the *Journal*, covering all material from January 1976 through December 1976. The complete citation for each article in the author index is listed under the name of the first author; joint authors are listed alphabetically with a cross-reference to the full citation. Book reviews appear in the author index under the name of the reviewer and in the subject index under the heading Books Reviewed; the books are arranged alphabetically by the surname of the book's first author.

Entries other than regular articles and brief communications are indicated as such by the following designations: editorial (editorial); letter to the editor (ltr to ed); in memoriam (in mem); and official actions (off acts).

Subject Index

ADOLESCENCE

Adolescent parricide: a comparison with other adolescent murder: BF Corder, BC Ball, TM Haizlip, R Rollins, R Beaumont, Aug, 957–961
The behavior of hypersexual delinquent girls, JD Goodman, June, 662–668
Evolution of behavior disorders into adolescence, A Thomas, S Chess, May, 539–542
Studies of adoptees from psychiatrically disturbed biological parents: III. Medical symptoms and illnesses in childhood and adolescence, RJ Cadoret, L Cunningham, R Loftus, J Edwards, Nov, 1316–1318
Training community-based paraprofessionals as behavior therapists with families of alcohol-abusing adolescents, JD Teicher, RD Sinay, JS Stumphauzer, July, 847–850
The treatment of anorexia nervosa, AR Lucus, JW Duncan, V Piens, Sept, 1034–1038
Virilizing influences, sexual behavior, and IQ (ltr to ed), V Abernethy, and reply of JD Goodman, Nov, 1350–1351

ADOPTION

The effects of the sealed record in adoption, AD Sorosky, A Baran, R Pannor, Aug, 900–904
A reconsideration of the Kety and associates study of genetic factors in the transmission of schizophrenia, LS Benjamin, Oct, 1129–1133
A reply to a rebuttal, LS Benjamin, Dec, 1466
Studies of adoptees from psychiatrically disturbed biological parents: III. Medical symptoms and illnesses in childhood and adolescence, RJ Cadoret, L Cunningham, R Loftus, J Edwards, Nov, 1316–1318
Studies designed to disentangle genetic and environmental variables in schizophrenia: some epistemological questions and answers, SS Kety, Oct, 1134–1137

AFFECTIVE DISORDERS

Agitated psychotic depression associated with severe hypomanic episodes: a rare syndrome, JM Himmelhoch, P Coble, DJ Kupfer, J Ingenito, July, 765–771; correction, Aug, 981
The course of development of mania in patients with recurrent depression, DL Dunner, JL Fleiss, RR Fieve, Aug, 905–908
A dopaminergic mechanism in mania, RH Gerner, RM Post, WE Bunney Jr, Oct, 1178–1180
ECT in the treatment of mania: a controlled study, MS McCabe, June, 688–691
A favorable response to lithium carbonate in a "schizo-affective" father and son, DE Reiser, AB Willett, July, 824–827
Lithium and affective disorders associated with organic brain impairment (ltr to ed), DB Mehta, Feb, 236
Lithium prophylaxis of depression in bipolar I, bipolar II, and unipolar patients, RR Fieve, T Kumbaraci, DL Dunner, Aug, 925–929
Lithium in the treatment of depression, J Mendels, April, 373–378
Mania and bromism: a case report and a look to the future, AJ Sayed, Feb, 228–229
Mania and schizo-affective disorder, manic type: a comparison, R Abrams, MA Taylor, Dec, 1445–1447
Marital therapy when one spouse has a primary affective disorder, BL Greene, N Lustig, RR Lee, July, 827–830
Overview: maintenance therapy in psychiatry: II. Affective disorders, JM Davis, Jan, 1–13
"Postmanic traumatic neurosis" (ltr to ed), R Benson, and reply of J Kotin, July, 862–863
On prophylaxis in unipolar affective disorder (ltr to ed), F Quitkin, A Rifkin, DF Klein, JM Davis, Sept, 1091–1092
Psychosis, thought disorder, and regression, NC Andreasen, PS Powers, May, 522–526
Relationship between dosage and response to lithium prophylaxis in recurrent depression, RF Prien, EM Caffey Jr, May, 567–570
Short versus long hospitalization: a prospective controlled study. V. One-year follow-up results for nonschizophrenic patients, ID Glick, W Hargreaves, J Drues, JA Showstack, May, 515–517
A therapeutic example (ltr to ed), RC Evans, Nov, 1346
Triple mosaicism of X chromosomes in bipolar affective disorder (ltr to ed), Y-t Kusumi, June, 719
The 24-hour lithium level as a prognosticator of dosage requirements: a 2-year follow-up study, TB Cooper, GM Simpson, April, 440–443

AGGRESSION

The effect of lithium on impulsive aggressive behavior in man, MH Sheard, JL Marini, CI Bridges, E Wagner, Dec, 1409–1413

ALBINISM

Albinism and schizophreniform psychosis: a pedigree study, M Baron, Sept, 1070–1073

ALCOHOL, ALCOHOLISM

Alcohol and drug abuse consultation in the general hospital: a systems approach, M Galanter, TB Karasu, JF Wilder, Aug, 930–934
The alcoholic physician: a survey, L Bissell, RW Jones, Oct, 1142–1146
Convulsions following disulfiram treatment (ltr to ed), TRP Price, Feb, 235
Craft versus profession in alcoholism treatment (ltrs to ed), M Galanter; R Peele; EM Scott, and reply of M Kalb, MS Propper, Nov, 1345–1346
The future of alcohology: craft or science? M Kalb, MS Propper, June, 641–645
The "intoxication state of consciousness": a model for alcohol and drug abuse, M Galanter, June, 635–640
Joint admission as a treatment modality for problem drinkers: a case report, TJ Paolino, BS McCrady, Feb, 222–224
More "craft versus science" (ltr to ed), TT Flynn, and reply of MS Propper, M Kalb, Dec, 1467–1468
Tracking difficulties and paranoid ideation during hashish and alcohol intoxication, FT Melges, Sept, 1024–1028
Training community-based paraprofessionals as behavior therapists with families of alcohol-abusing adolescents, JD Teicher, RD Sinay, JS Stumphauzer, July, 847–850

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY

The American Board of Psychiatry and Neurology (off acts), May, 606–608

The American Board of Psychiatry and Neurology (off acts), June, 736
The American Board of Psychiatry and Neurology (off acts), Aug, 991–994
The American Board of Psychiatry and Neurology (off acts), Nov, 1366–1368
Certification for foreign medical graduates (ltr to ed), AK Nafees, Feb, 233–234
Commission on Certification in Administrative Psychiatry (off acts), Aug, 994
In defense of the Boards (ltr to ed), AE Rainess, and reply of MR Lipp, Oct, 1207–1208
Experiences of psychiatry Board exam casualties: a survey report, MR Lipp, March, 279–283
Feedback on the Boards (ltr to ed), MF Heiman, Dec, 1471
1975 annual report of the American Board of Psychiatry and Neurology, Inc (off acts), LH Rudy, Oct, 1246–1250
On the Boards again (ltr to ed), GP Congram, June, 718
We're still on the Boards (ltr to ed), MR Gaitonde, Aug, 979–980

AMERICAN JOURNAL OF PSYCHIATRY

Editing circa 1976 (editorial), FJ Braceland, Jan, 76–79

AMERICAN PSYCHIATRIC ASSOCIATION

The Assembly of District Branches (off acts), April, 487–488
The behavior therapies: therapeutic breakthrough or latest fad? AK Shapiro, Feb, 154–159
The Council on Emerging Issues (off acts), JM Lewis, April, 487
The Council on Internal Organization (off acts), M Greenblatt, April, 484–486
The Council on International Affairs (off acts), N Rosenzweig, April, 481–482
The Council on Medical Education and Career Development (off acts), RI Shader, April, 473–475
The Council on Mental Health Services (off acts), JC Johnson, April, 475–477
The Council on National Affairs (off acts), HM Visotsky, April, 480–481
The Council on Professions and Associations (off acts), RI Barnard, April, 482–483
The Council on Research and Development (off acts), LJ West, April, 477–479
Editing circa 1976 (editorial), FJ Braceland, Jan, 76–79
Highlights of the 129th annual meeting (off acts), JH Masserman, July, 880–882
Impact of a district branch task force on women, E Hilberman, M Gispert, J Harper, Oct, 1159–1164
Insuring psychiatrists (ltrs to ed), G Bajor; B Lipton, and reply of CL Trent, June, 713–714
Judd Marmor, MD, one hundred and fourth President, 1975–1976, M Sabshin, July, 748–751
An opportunity to stimulate self-evaluation and learning (editorial), SL Werkman, Feb, 215–216
Peer review and PSRO: an update, FW Sullivan, Jan, 51–55
Position statement on administration of psychiatric facilities (off acts), May, 604
Position statement on desegregation of hospitals for the mentally ill and retarded (off acts), May, 603
Position statement on mental health representation in governance and staffing of health systems agencies (off acts), May, 601–602
Position statement on the quality of life (off acts), May, 603
Position statement on the training of minority psychiatrists (off acts), May, 605
Presidential address: psychiatry 1976—the continuing revolution, J Marmor, July, 739–745; correction, Sept, 1097
Psychiatry, cafeteria-style (ltr to ed), L Sederer, Sept, 1093
Report of the Committee of Tellers (off acts), EA Hargrove, Oct, 1244
Report of the Medical Director (off acts), M Sabshin, Oct, 1236–1240
Report of the Membership Committee (off acts), LE Morrow, Oct, 1245
Report of the Secretary: summary of meetings of Board of Trustees and Executive Committee, May 1975–May 1976 (off acts), JH Masserman, Oct, 1223–1231
Report of the Speaker (off acts), ML Zaphiropoulos, Oct, 1241–1242
Report of the Speaker-Elect (off acts), IN Perr, Oct, 1243
Report of the Treasurer (off acts), J Weinberg, Oct, 1232–1235
Response to the Presidential address, RW Gibson, July, 746–747

ANIMAL STUDIES

Diazepam treatment of socially isolated monkeys, AB Noble, WT McKinney Jr, C Mohr, E Moran, Oct, 1165–1170
Social rehabilitation of separation-induced depressive disorders in monkeys, SJ Suomi, R DeLizio, HF Harlow, Nov, 1279–1285

ANXIETY

Coffee consumption among psychiatric inpatients, DK Winstead, Dec, 1447–1450
The treatment of pathological panic states with propranolol, JF Heiser, D DeFrancisco, Dec, 1389–1394

AUTISM

Correlation or causation: neuropathophysiology and autism (ltr to ed), HN Massie, and reply of ER Ritvo, EM Ornitz, Dec, 1468–1469
The syndrome of autism: a critical review, EM Ornitz, ER Ritvo, June, 609–621

BEHAVIOR THERAPY

The behavior therapies: therapeutic breakthrough or latest fad? AK Shapiro, Feb, 154–159
Behavior therapy and sex therapy, JP Brady, Aug, 896–899
Behavioral theory in psychiatric education (ltr to ed), OG Cameron, Aug, 977
A behaviorist omitted? (ltr to ed), EM Scott, and reply of I Marks, Sept, 1091
The current status of behavioral psychotherapy: theory and practice, IM Marks, March, 253–261
Management of interpersonal issues in systematic desensitization, DL Braff, M Raskin, D Geisinger, July, 791–794
Siblings as therapists: a behavioral approach, NB Miller, DP Cantwell, April, 447–450
Training community-based paraprofessionals as behavior therapists with families of alcohol-abusing adolescents, JD Teicher, RD Sinay, JS Stumphauzer, July, 847–850
Treatment for the parents of feminine boys, E Newman, June, 683–687
An unfair indictment of behavior therapies? (ltr to ed), JP Brady, and reply of AK Shapiro, July, 852–853

BEREAVEMENT

We help each other: primary prevention for the widowed, WF McCourt, RD Barnett, J Brennen, A Becker, Jan, 98–100

BIOCHEMICAL STUDIES

Albinism and schizophreniform psychosis: a pedigree study, M Baron, Sept, 1070–1073
Clinical response and plasma levels: effect of dose, dosage schedules, and drug interactions on plasma chlorpromazine levels, L Rivera-Calimlim, H Nasrallah, J Strauss, L Lasagna, June, 646–652
Cocaine, kindling, and psychosis, RW Post, RT Kopanda, June, 627–634
Decreased blood platelet MAO activity in unmedicated chronic schizophrenic patients, EF Domino, SS Khanna, March, 323–326; correction, June, 720
The dopamine hypothesis of schizophrenia: focus on the dopamine receptor, SH Snyder, Feb, 197–202
A dopaminergic mechanism in mania, RH Gerner, RM Post, WE Bunney Jr, Oct, 1178–1180
The effect of marijuana on carbohydrate metabolism, MA Permutt, DW Goodwin, R Schwin, SY Hill, Feb, 220–222
Immunoglobulin levels in psychiatric patients, M Strahilevitz, JB Fleischman, GW Fischer, N Narasimhachari, July, 772–777
Importance of dopamine metabolism for clinical effects and side effects of neuroleptics, HM van Praag, J Korf, Oct, 1171–1177
Mania and bromism: a case report and a look to the future, AJ Sayed, Feb, 228–229
Negative effects of melatonin on depression, JS Carman, RM Post, R Buswell, FK Goodwin, Oct, 1181–1186
Platelet monoamine oxidase activity in schizophrenia, HL White, MN McLeod, JRT Davidson, Oct, 1191–1193
Prolactin secretion and antipsychotic efficacy (ltr to ed), PH Gruen, EJ Sachar, and reply of JM Davis, Sept, 1090
The psychedelic model of schizophrenia: the case of *N,N*-dimethyltryptamine, JC Gillin, J Kaplan, R Stillman, RJ Wyatt, Feb, 203–208
Red blood cell catechol *O*-methyltransferase and response to imipramine in unipolar depressive women, JRT Davidson, MN McLeod, HL White, D Raft, Aug, 952–955
Reduced platelet monoamine oxidase activity in a subgroup of schizophrenic patients, JJ Schildkraut, JM Herzog, PJ Orsulak, SE Edelman, HM Shein, SH Frazier, April, 438–440
The reversal of tricyclic-overdosage-induced central anticholinergic syndrome by physostigmine, PC Holinger, HL Klawans, Sept, 1018–1023
Serum creatine phosphokinase in schizophrenia, HY Meltzer, Feb, 192–197
A theory of "psychogenic polydipsia" (ltr to ed), A Kubacki, July, 853–854
Thyrotropin-releasing hormone: differential antidepressant and endocrinological effects, FW Furlong, GM Brown, MF Beeching, Oct, 1187–1190

BOOK REVIEWS, RESPONSES TO

In defense of a second edition (ltrs to ed), F Kline; H Grunebaum, Oct, 1208

BORDERLINE SYNDROME

Regression and borderline patients (ltr to ed), J Spensley, and reply of HJ Friedman, April, 453

CANCER

Cancer, emotions, and mental illness: the present state of understanding, FG Surawicz, DR Brightwell, WD Weitzel, E Othmer, Nov, 1306–1309
Rauwolfia derivatives and breast cancer (ltr to ed), A Jus, R Pineau, N Hazz, April, 451–452

CAPGRAS SYNDROME

Capgras syndrome: a case involving violence (ltr to ed), R Weinstock, July, 855
More violent Capgras (ltr to ed), DL Crane, Nov, 1350

CATATONIA

Catatonia, gastric hyperacidity, and fatal aspiration: a preventable syndrome, RF Bort, April, 446–447
Catatonialike symptomatology and withdrawal dyskinesias, MI Good, Dec, 1454–1456
Fatal aspiration (ltr to ed), K Solomon, and reply of RF Bort, Nov, 1349–1350

CERTIFICATION

Competency-based psychiatric education, HM Weinstein, ML Russell, Aug, 935–939
Experiences of psychiatry Board exam casualties: a survey report, MR Lipp, March, 279–283
Feedback on the Boards (ltr to ed), MF Heiman, Dec, 1471
In defense of the Boards (ltr to ed), AE Rainess, and reply of MR Lipp, Oct, 1207–1208
On the Boards again (ltr to ed), GP Congram, June, 718
We're still on the Boards (ltr to ed), MR Gaitonde, Aug, 979–980

CHILDREN AND CHILD PSYCHIATRY

Behavioral characteristics of children with chronic nonspecific diarrhea, EH Wender, FB Palmer, JJ Herbst, PH Wender, Jan, 20–25
Child custody contests in historical perspective, AP Derdeyn, Dec, 1369–1376
Children of disaster: clinical observations at Buffalo Creek, CJ Newman, March, 306–312
Correlation or causation: neuropathophysiology and autism (ltr to ed), HN Massie, and reply of ER Ritvo, EM Ornitz, Dec, 1468–1469
Delinquency, psychomotor epileptic symptoms, and paranoid ideation: a triad, DO Lewis, Dec, 1395–1398
Depressive disorder in childhood (ltr to ed), RA Brumback, and reply of RL Spitzer, April, 455–456
The effects of the sealed record in adoption, AD Sorosky, A Baran, R Pannor, Aug, 900–904
Evolution of behavior disorders into adolescence, A Thomas, S Chess, May, 539–542
The family and schizophrenia, D Reiss, Feb, 181–185
Lead and hyperactivity. Behavioral response to chelation: a pilot study, OJ David, SP Hoffman, J Sverd, J Clark, K Voeller, Oct, 1155–1158
Linguistic performance in vulnerable and autistic children and their mothers, SM Frank, DA Allen, L Stein, B Myers, Aug, 909–915
The murdered child and his killers, D Kaplun, R Reich, July, 809–813
A problem of methodology? (ltr to ed), AW Mariner, and reply of BD Garfinkel, CD Webster, L Sloman, March, 345–346
Reporting side effects of imipramine in children (ltr to ed), HR Huessy, and reply of LM Greenberg, AM Yellin, June, 715
Siblings as therapists: a behavioral approach, NB Miller, DP Cantwell, April, 447–450
The significance of childhood neurosis for adult mental health: a follow-up study, S Waldron Jr, May, 532–538
"Sociopathy" and child psychiatry (ltr to ed), AF Kinzel, and reply of DO Lewis, DA Balla, Jan, 102–103
Studies of adoptees from psychiatrically disturbed biological parents: III. Medical symptoms and illnesses in childhood and adolescence, RJ Cadoret, L Cunningham, R Loftus, J Edwards, Nov, 1316–1318
The syndrome of autism: a critical review, EM Ornitz, ER Ritvo, June, 609–621
Treatment for the parents of feminine boys, LE Newman, June, 683–687
Was "sociopathy" ever a diagnosis? (ltr to ed), RL Jenkins, and reply of DO Lewis, April, 456–457

COMMUNITY CARE FACILITIES

Community alternatives to institutional care, LD Ozarin, Jan, 69–72
A five-year study of brief hospitalization, M Swartzburg, A Schwartz, Aug, 922–924
Limitations of brief hospital treatment, S Reibel, MI Herz, May, 518–521
Prospective studies on released inpatients (ltr to ed), G Barton, July, 865

A symposium: follow-up studies of community care, M Greenblatt, RD Budson (eds), Aug, 916–921

COMMUNITY MENTAL HEALTH

Can program evaluation be saved from its enthusiasts? J Zusman, Nov, 1300–1305
Community alternatives to institutional care, LD Ozarin, Jan, 69–72
Community mental health center legislation: flight of the phoenix, FM Ochberg, Jan, 56–61
Correlates of patient attendance in an inner-city mental health clinic, TJ Craig, CL Huffine, Jan, 61–65
Crime and violence among mental patients, A Zitrin, AS Hardesty, EI Burdock, AK Drossman, Feb, 142–149
A note on some recent studies of released mental hospital patients in the community, LL Bachrach, Jan, 73–75
Patient privacy and confidentiality at mental health centers, JO Noll, MJ Hanlon, Nov, 1286–1289
Peer review of prescribing patterns in a CMHC, H Diamond, R Tislow, T Snyder Jr, K Rickels, June, 697–699
A program problem? (ltr to ed), K Solomon, and reply of J Yager, RO Pasnau, Sept, 1095
The psychiatric resident as an ex-officio community board member, A Beigel, R Bevan, J LaWall, J Orttung, D Westin, Oct, 1200–1202
Psychiatry and folk healing: a dichotomy? P Ruiz, J Langrod, Jan, 95–97
Services for the aged in community mental health centers, RD Patterson, March, 271–273
A symposium: follow-up studies of community care, M Greenblatt, RD Budson (eds), Aug, 916–921
Training community-based paraprofessionals as behavior therapists with families of alcohol-abusing adolescents, JD Teicher, RD Sinay, JS Stumphauzer, July, 847–850
Trends in hospital versus community treatment of mental illness: a Texas example, JL Claghorn, GW McBee, L Roberts, Nov, 1310–1312
The use of problem-oriented medical records in community mental health centers, GM Vickar, M Herjanic, March, 340–341
The use of two-way TV in bringing mental health services to the inner city, N Straker, P Mostyn, C Marshall, Oct, 1202–1205

COMPUTERS

Computerized tomography in patients with tardive dyskinesia, AJ Gelenberg, May, 578–579
Routine on-line psychiatric diagnosis by computer, JH Greist, MH Klein, HP Erdman, Dec, 1405–1408

CONFIDENTIALITY

Confidentiality in military psychiatry (ltr to ed), J Wilf, July, 864
Patient privacy and confidentiality at mental health centers, JO Noll, MJ Hanlon, Nov, 1286–1289

CONSULTATION, PSYCHIATRIC

Alcohol and drug abuse consultation in the general hospital: a systems approach, M Galanter, TB Karasu, JF Wilder, Aug, 930–934
Consultation-liaison psychiatry: current responsibilities, WA Brown, EM Jacobson, March, 326–328
Occurrence of psychiatric disorder in a county jail population, GE Swank, D Winer, Nov, 1331–1333
Psychiatric disturbances of aged patients in skilled nursing homes, RB Teeter, FK Garetz, WR Miller, WF Heiland, Dec, 1430–1434
The psychiatrist and the pain clinic, I Pilowsky, July, 752–756
A violence clinic: three years' experience, JR Lion, DJ Madden, RL Christopher, April, 432–435

COPING MECHANISMS

Coping behavior of the rape victim, AW Burgess, LL Holmstrom, April, 413–418
Family and character change at Buffalo Creek, JL Titchener, FT Kapp, March, 295–299
The family in exile: Cuban expatriates in the United States, RD Rumbaut, RG Rumbaut, April, 395–399
The functions and regulation of the arousal of anger, RW Novaco, Oct, 1124–1128
The interaction of social class and other factors in the etiology of schizophrenia, ML Kohn, Feb, 177–180

CREATIVITY

Death, creativity, and depression (ltr to ed), TE Passman, April, 451
More on creativity (ltr to ed), A Rothenberg, Sept, 1090–1091

CRIME

Crime and violence among mental patients, A Zitrin, AS Hardesty, EI Burdock, AK Drossman, Feb, 142–149
Examining the pavement (ltr to ed), SL Auster, and reply of A Zitrin, AS Hardesty, EI Burdock, AK Drossman, July, 863–864

CRISIS INTERVENTION

Chronic callers to a crisis center (ltr to ed), AJ Dy, J van Lopik, Aug, 977–978
Development of a medical center rape crisis intervention program, SL McCombie, E Bassuk, R Savitz, S Pell, April, 418–421
Peer counseling in a general hospital, FG Guggenheim, S O'Hara, Oct, 1197–1199
We help each other: primary prevention for the widowed, WF McCourt, RD Barnett, J Brennen, A Becker, Jan, 98–100

DEATH

Cancer, emotions, and mental illness: the present state of understanding, FG Surawicz, DR Brightwell, WD Weitzel, E Othmer, Nov, 1306–1309
Death, creativity, and depression (ltr to ed), TE Passman, April, 451
Death fantasies as an escape mechanism (ltr to ed), W Bromberg, and reply of RJ Cohen, Nov, 1348–1349
The fatal myth of death in the family, EM Pattison, June, 674–678

DELIVERY SYSTEMS, MENTAL HEALTH

Alcohol and drug abuse consultation in the general hospital: a systems approach, M Galanter, TB Karasu, JF Wilder, Aug, 930–934
A five-year study of brief hospitalization, M Swartzburg, A Schwartz, Aug, 922–924
The life of psychiatry, BS Brown, May, 489–495
Mental health services and the elderly: needs and options, GD Cohen, Jan, 65–68
Mental health services in the public and private sectors, LM Koran, Sept, 1052–1057

Occurrence of psychiatric disorder in a county jail population, GE Swank, D Winer, Nov, 1331–1333
Position statement on administration of psychiatric facilities (off acts), May, 604
Position statement on mental health representation in governance and staffing of health systems agencies (off acts), May, 601–602
Position statement on the training of minority psychiatrists (off acts), May, 605
Psychiatric disturbances of aged patients in skilled nursing homes, RB Teeter, FK Garetz, WR Miller, WF Heiland, Dec, 1430–1434
Services for the aged in community mental health centers, RD Patterson, March, 271–273
Student mental health services and departments of psychiatry, CB Reifler, R Babineau, Aug, 967–968
A symposium: follow-up studies of community care, M Greenblatt, RD Budson (eds), Aug, 916–921
The use of two-way TV in bringing mental health services to the inner city, N Straker, P Mostyn, C Marshall, Oct, 1202–1205
Utilization of prepaid services by patients with psychiatric diagnoses, DT Fullerton, FN Lohrenz, GR Nyca, Sept, 1057–1060

DEPERSONALIZATION

Self-induced depersonalization syndrome, RB Kennedy Jr, Nov, 1326–1328

DEPRESSION

Agitated psychotic depression associated with severe hypomanic episodes: a rare syndrome, JM Himmelhoch, P Coble, DJ Kupfer, J Ingenito, July, 765–771; correction, Aug, 981
Clinical depression among narcotic addicts maintained on methadone in the community, MM Weissman, F Slobetz, B Prusoff, M Mezritz P Howard, Dec, 1434–1438
The concept of drug automatism, MI Good, Aug, 948–952
The course of development of mania in patients with recurrent depression, DL Dunner, JL Fleiss, RR Fieve, Aug, 905–908
Death, creativity, and depression (ltr to ed), TE Passman, April, 451
Depression and the reintegration phase of acute schizophrenia, PT Donlon, RT Rada, KK Arora, Nov, 1265–1268
Depressive disorder in childhood (ltr to ed), RA Brumback, and reply of RL Spitzer, April, 455–456
Drug and psychotherapy interactions in depression, L Covi, RS Lipman, RD Alarcon, VK Smith, May, 502–508
EEG sleep changes as predictors in depression, DJ Kupfer, FG Foster, L Reich, KS Thompson, B Weiss, June, 622–626
The fatal myth of death in the family, EM Pattison, June, 674–678
Follow-up of depressed women after maintenance treatment, MM Weissman, SV Kasl, GL Klerman, July, 757–760
An investigation of the postpsychotic depressive syndrome, TH McGlashan, WT Carpenter Jr, Jan, 14–19
Lithium and depression (ltr to ed), RO Friedel, Aug, 976
Lithium prophylaxis of depression in bipolar I, bipolar II, and unipolar patients, RR Fieve, T Kumbaraci, DL Dunner, Aug, 925–929
Lithium in the treatment of depression, J Mendels, April, 373–378
Negative effects of melatonin on depression, JS Carman, RM Post, R Buswell, FK Goodwin, Oct, 1181–1186
Overview: maintenance therapy in psychiatry: II. Affective disorders, JM Davis, Jan, 1–13
Presence and persistence of depressive symptoms in patient and community populations, TJ Craig, PA Van Natta, Dec, 1426–1429
A psychiatric study of patients referred with a diagnosis of hypoglycemia, CV Ford, GA Bray, RS Swerdloff, March, 290–294
Psychiatric test assessment of patients with psychomotor epilepsy, EA Serafetinides, DG Cherlow, July, 844–847
Red blood cell catechol *O*-methyltransferase and response to imipramine in unipolar depressive women, JRT Davidson, MN McLeod, HL White, D Raft, Aug, 952–955
Relationship between dosage and response to lithium prophylaxis in recurrent depression, RF Prien, EM Caffey Jr, May, 567–570
Social rehabilitation of separation-induced depressive disorders in monkeys, SJ Suomi, R DeLizio, HF Harlow, Nov, 1279–1285
Thiothixene and the postpsychotic depressive syndrome (ltr to ed), VF Ognyanov, and reply of TH McGlashan, WT Carpenter Jr, July, 861–862
Thyrotropin-releasing hormone: differential antidepressant and endocrinological effects, FW Furlong, GM Brown, MF Beeching, Oct, 1187–1190
Treating depression in patients with cardiovascular problems (ltr to ed), RM Allen, July, 855–856
"Waltons syndrome" (ltr to ed), FJ Whelan, June, 719–720

DEVELOPMENTAL THEORY

Children of disaster: clinical observations at Buffalo Creek, CJ Newman, March, 306–312
Evolution of behavior disorders into adolescence, A Thomas, S Chess, May, 539–542

DIAGNOSIS

Agitated psychotic depression associated with severe hypomanic episodes: a rare syndrome, JM Himmelhoch, P Coble, DJ Kupfer, J Ingenito, July, 765–771; correction, Aug, 981
Current diagnostic concepts in schizophrenia, WT Carpenter Jr, Feb, 172–177
Depressive disorder in childhood (ltr to ed), RA Brumback, and reply of RL Spitzer, April, 455–456
Diagnosis and treatment in a case of tardive dyskinesia (ltr to ed), RA Kuwik, MJ Steinhardt, and reply of DE Casey, D Denney, March, 346–347
Encephalopathy and psychiatric diagnosis (ltrs to ed), CE Wells; R Malcolm, and reply of LG Wilson, July, 859–860
Etiology and differential diagnosis of the morbid jealousies (ltr to ed), CG Dunn, and reply of JP Docherty, Nov, 1346–1347
Hypothalamic tumor presenting as anorexia nervosa, GB Heron, DA Johnston, May, 580–582
The identification and treatment of adult brain dysfunction, HB Mann, SI Greenspan, Sept, 1013–1017
Mania and schizo-affective disorder, manic type: a comparison, R Abrams, MA Taylor, Dec, 1445–1447
Methodology and personality in Briquet's syndrome: a reappraisal, MJ Kaminsky, PR Slavney, Jan, 85–88
Preciseness in diagnostic terminology (ltr to ed), H Bruch, Sept, 1093
Problems in the differential diagnosis of narcolepsy versus schizophrenia, B Shapiro, H Spitz, Nov, 1321–1323
Psychiatric presentations of seizure disorders, J LaWall, March, 321–323
Questioning a diagnosis (ltrs to ed), JW Jefferson; M Abbas, and reply of AJ Sayed, Oct, 1208–1209
Routine on-line psychiatric diagnosis by computer, JH Greist, MH Klein, HP Erdman, Dec, 1405–1408
In search of the true amok: amok as viewed within the Malay culture, JE Carr, EK Tan, Nov, 1295–1299
Sex therapy and psychophysiological research, RC Schiavi, May, 562–566
The syndrome of autism: a critical review, EM Ornitz, ER Ritvo, June, 609–621
Treatment plans for mental health care, DJ Knesper, D Miller, Jan, 45–50
Viral encephalopathy mimicking functional psychosis, LG Wilson, Feb, 165–170
Was "sociopathy" ever a diagnosis? (ltr to ed), RL Jenkins, and reply of DO Lewis, April, 456–457

DREAMS

Do dreams have meaning? An empirical inquiry, M Kramer, R Hlasny, G Jacobs, T Roth, July, 778–781
Pavor nocturnus: a complication of single daily tricyclic or neuroleptic dosage, A Flemenbaum, May, 570–572
REM sleep and adaptation of psychiatric patients: an application of sleep studies, R Greenberg, CA Pearlman Jr, Oct, 1147–1150

DRUG ABUSE

Alcohol and drug abuse consultation in the general hospital: a systems approach, M Galanter, TB Karasu, JF Wilder, Aug, 930–934
Chronic hashish use and mental disorder, C Stefanis, A Liakos, J Boulougouris, M Fink, AM Freedman, Feb, 225–227
Effects of legal pressure on prognosis for treatment of drug dependence, RJ Harford, JC Ungerer, JK Kinsella, Dec, 1399–1404
An evaluation of detoxification as an initial step in the treatment of heroin addiction, A Sheffet, M Quinones, MA Lavenhar, K Doyle, H Prager, March, 337–340
The "intoxication state of consciousness": a model for alcohol and drug abuse, M Galanter, June, 635–640
l-Alpha-acetylmethadol (LAAM): prognostic considerations, RB Resnick, L Orlin, G Geyer, E Schuyten-Resnick, RS Kestenbaum, AM Freedman, July, 814–819
Mania and bromism: a case report and a look to the future, AJ Sayed, Feb, 228–229
Marijuana and hostility in a small-group setting, C Salzman, BA Van der Kolk, RI Shader, Sept, 1029–1033
The natural history of "chipping," NE Zinberg, RC Jacobson, Jan, 37–40
Neuropsychological and EEG disturbances in polydrug users, I Grant, LL Judd, Sept, 1039–1042
Treatment of accidental naltrexone-induced withdrawal (ltr to ed), J Volavka, RB Resnick, Feb, 233

DRUG SIDE EFFECTS

Amantadine versus trihexyphenidyl in the treatment of neuroleptic-induced parkinsonism, WE Fann, CR Lake, Aug, 940–943
Anticholinergic exacerbation of phenothiazine-induced extrapyramidal syndrome, M Alpert, F Diamond, EM Laski, Sept, 1073–1075
Antiparkinsonian agents and fluphenazine decanoate, S Idzorek, Jan, 80–82
The behavior of hypersexual delinquent girls, JD Goodman, June, 662–668
Catatonialike symptomatology and withdrawal dyskinesias, MI Good, Dec, 1454–1456
Cocaine, kindling, and psychosis, RM Post, RT Kopanda, June, 627–634
Cogwheel rigidity early in lithium therapy (ltr to ed), RD Bien, and reply of B Shopsin, S Gershon, Sept, 1093–1094
Combining lithium and neuroleptics (ltr to ed), JS Brust, and reply of B Shopsin, JG Small, JJ Kellams, V Milstein, JE Moore, Aug, 980–981
Computerized tomography in patients with tardive dyskinesia, AJ Gelenberg, May, 578–579
The concept of drug automatism, MI Good, Aug, 948–952
Confirming a side effect (ltr to ed), MA Amdur, July, 864–865
Convulsions following disulfiram treatment (ltr to ed), TRP Price, Feb, 235
Digit-symbol performance in methadone-treated ex-heroin addicts, PW Appel, NB Gordon, Nov, 1337–1339
"Equivalent" doses in medication changes (ltr to ed), GL LaVigne, RJ Baldessarini, July, 851–852
Extrapyramidal side effects in lithium maintenance therapy, MH Branchey, J Charles, GM Simpson, April, 444–445
Failure of deanol in treating tardive dyskinesia (ltr to ed), D Mehta, S Mehta, P Mathew, Dec, 1467
Hiccups following ingestion of oral chlordiazepoxide (ltr to ed), DK Winstead, June, 719
Importance of dopamine metabolism for clinical effects and side effects of neuroleptics, HM van Praag, J Korf, Oct, 1171–1177
Low urinary dopamine and prediction of phenothiazine-induced parkinsonism: a preliminary report, TJ Crowley, CO Rutledge, MM Hoehn, MA Stallings, S Sundell, June, 703–706
Maintenance antipsychotic therapy: is the cure worse than the disease? G Gardos, J Cole, Jan, 32–36
Marijuana effects on simulated flying ability, DS Janowsky, MP Meacham, JD Blaine, M Schoor, LP Bozzetti, April, 384–388
Marijuana and hostility in a small-group setting, C Salzman, BA Van der Kolk, RI Shader, Sept, 1029–1033
A medical student's experience with akisthisia (ltr to ed), KS Kendler, April, 454–455
A methodological question (ltr to ed), AJ Gelenberg, MR Mandel, and reply of S Idzorek, July, 860–861
More on neuromuscular side effects of antipsychotics (ltr to ed), AJ Gelenberg, and reply of HR Barton, Sept, 1089–1090
Neuromuscular side effects of antipsychotic drugs (ltr to ed), HR Barton, Jan, 106–107
Pavor nocturnus: a complication of single daily tricyclic or neuroleptic dosage, A Flemenbaum, May, 570–572
Penfluridol in the treatment of newly admitted schizophrenic patients in a brief therapy unit, G Chouinard, A Lawrence, July, 820–823
Rauwolfia derivatives and breast cancer (ltr to ed), A Jus, R Pineau, N Hazzi, April, 451–452
Reporting side effects of imipramine in children (ltr to ed), HR Huessy, and reply of LM Greenberg, AM Yellin, June, 715
The reversal of tricyclic-overdosage-induced central anticholinergic syndrome by physostigmine, PC Holinger, HL Klawans, Sept, 1018–1023
Somnambulism and bedtime medication (ltr to ed), L Huapaya, Oct, 1207
Therapeutic effects of methadone and *l*-α-acetylmethadol, E Karp-Gelernter, L Wurmser, C Savage, Aug, 955–957
Thioridazine and sexual dysfunction, J Kotin, DE Wilbert, D Verburg, SM Soldinger, Jan, 82–85
Treating depression in patients with cardiovascular problems (ltr to ed), RM Allen, July, 855–856
Treatment of accidental naltrexone-induced withdrawal (ltr to ed), J Volavka, RB Resnick, Feb, 233
Treatment of excessive weight gain in patients taking lithium, GM Dempsey, DL Dunner, RR Fieve, T Farkas, J Wong, Sept, 1082–1084

DRUG TREATMENT PROGRAMS

Clinical depression among narcotic addicts maintained on methadone in the community, MM Weissman, F Slobetz, B Prusoff, M Mezritz, P Howard, Dec, 1434–1438
Digit-symbol performance in methadone-treated ex-heroin addicts, PW Appel, NB Gordon, Nov, 1337–1339
Effects of legal pressure on prognosis for treatment of drug dependence, RJ Harford, JC Ungerer, JK Kinsella, Dec, 1399–1404
An evaluation detoxification as an initial step in the treatment of heroin addiction, A Sheffet, M Quinones, MA Lavenhar, K Doyle, H Prager, March, 337–340
l-Alpha-acetylmethadol (LAAM): prognostic considerations, RB Resnick, L Orlin, G Geyer, E Schuyten-Resnick, RS Kestenbaum, AM Freedman, July, 814–819
Therapeutic effects of methadone and *l*-α-acetylmethadol, E Karp-Gelernter, L Wurmser, C Savage, Aug, 955–957

DRUGS, RESEARCH AND USE

General

Effect of drug ritual changes on schizophrenic patients, RW Burgoyne, March, 284–289
Peer review of prescribing patterns in a CMHC, H Diamond, R Tislow, T Snyder Jr, K Rickels, June, 697–699

Antianxiety Agents

Diazepam treatment of socially isolated monkeys, AB Noble, WT McKinney Jr, C Mohr, E Moran, Oct, 1165–1170
Economics and ethics (ltr to ed), RL Goldstein, and reply of MH Keeler, RL McCurdy, Jan, 102
Hiccups following ingestion of oral chlordiazepoxide (ltr to ed), DK Winstead, June, 719

Anticonvulsants

Diphenylhydantoin treatment of bulimia (ltr to ed), T Weiss, L Levitz, Sept, 1093

Antidepressants

Drug and psychotherapy interactions in depression, L Covi, RS Lipman, RD Alarcon, VK Smith, May, 502–508
EEG sleep changes as predictors in depression, DJ Kupfer, FG Foster, L Reich, KS Thompson, B Weiss, June, 622–626
Follow-up of depressed women after maintenance treatment, MM Weissman, SV Kasl, GL Klerman, July, 757–760
Overview: maintenance therapy in psychiatry: II. Affective disorders, JM Davis, Jan, 1–13
Pavor nocturnus: a complication of single daily tricyclic or neuroleptic dosage, A Flemenbaum, May, 570–572
Red blood cell catechol *O*-methyltransferase and response to imipramine in unipolar depressive women, JRT Davidson, MN McLeod, HL White, D Raft, Aug, 952–955
Reporting side effects of imipramine in children (ltr to ed), HR Huessy, and reply of LM Greenberg, AM Yellin, June, 715
The reversal of tricyclic-overdosage-induced central anticholinergic syndrome by physostigmine, PC Holinger, HL Klawans, Sept, 1018–1023
Treating depression in patients with cardiovascular problems (ltr to ed), RM Allen, July, 855–856
Treatment of tricyclic intoxication, RA Munoz, Sept, 1085–1087

Antiparkinsonian Agents

Amantadine versus trihexyphenidyl in the treatment of neuroleptic-induced parkinsonism, WE Fann, RC Lake, Aug, 940–943
Antiparkinsonian agents and fluphenazine decanoate, S Idzorek, Jan, 80–82

Antipsychotic Agents

Anticholinergic exacerbation of phenothiazine-induced extrapyramidal syndrome, M Alpert, F Diamond, EM Laski, Sept, 1073–1075
Antiparkinsonian agents and fluphenazine decanoate, S Idzorek, Jan, 80–82
Clinical response and plasma levels: effects of dose, dosage schedules, and drug interactions on plasma chlorpromazine levels, L Rivera-Calimlim, H Nasrallah, J Strauss, L Lasagna, June, 646–652
Combining lithium and neuroleptics (ltr to ed), JS Brust, and reply of B Shopsin, JG Small, JJ Kellams, V Milstein, JE Moore, Aug, 980–981
Confirming a side effect (ltr to ed), MA Amdur, July, 864–865
Depression and the reintegration phase of acute schizophrenia, PT Donlon, RT Rada, KK Arora, Nov, 1265–1268
Diagnosis and treatment in a case of tardive dyskinesia (ltr to ed), RA Kuwik, MJ Steinhart, and reply of DE Casey, D Denney, March, 345–347
The dopamine hypothesis of schizophrenia: focus on the dopamine receptor, SH Snyder, Feb, 197–202
Effect of drug ritual changes on schizophrenic patients, RW Burgoyne, March, 284–289
The effect of haloperidol on stuttering, PB Rosenberger, JA Wheelden, M Kalotkin, March, 331–334
"Equivalent" doses in medication changes (ltr to ed), GL LaVigne, RJ Baldessarini, July, 851–852
An error corrected (ltr to ed), CN Brownsberger, and reply of JM Davis, July, 865
A follow-up of 78 patients with Gilles de la Tourette's syndrome, RD Bruun, AK Shapiro, E Shapiro, R Sweet, H Wayne GE Solomon, Aug, 944–947
Generic and trade-name antipsychotic drugs: clinical equivalence, C-p Chien, R LaBrie, C-g Park, JO Cole, W Werner, Dec, 1377–1381
Homeopathic dosage in maintenance therapy (ltr to ed), G Middlkauff, and reply of JM Davis, July, 857
Importance of dopamine metabolism for clinical effects and side effects of neuroleptics, HM van Praag, J Korf, Oct, 1171–1177
Low urinary dopamine and prediction of phenothiazine-induced parkinsonism: a preliminary report, TJ Crowley, CO Rutledge, MM Hoehn, MA Stallings, S Sundell, June, 703–706
Maintenance antipsychotic therapy: is the cure worse than the disease? G Gardos, JO Cole, Jan, 32–36
Maintenance therapy guidelines (ltr to ed), K Solomon, and reply of JM Davis, July, 857–858
A methodological question (ltr to ed), AJ Gelenberg, MR Mandel, and reply of S Idzorek, July, 860–861
More on fluphenazine and polypharmacy (ltr to ed), A DiMascio, and reply of G Chouinard, Jan, 105–106
More on neuromuscular side effects of antipsychotics (ltr to ed), AJ Gelenberg, and reply of HR Barton, Sept, 1089–1090
Neuromuscular side effects of antipsychotic drugs (ltr to ed), HR Barton, Jan, 106–107
Pavor nocturnus: a complication of single daily tricyclic or neuroleptic dosage, A Flemenbaum, May, 570–572
Penfluridol in the treatment of newly admitted schizophrenic patients in a brief therapy unit, G Chouinard, L Annable, July, 820–823
Prolactin secretion and antipsychotic efficacy (ltr to ed), PH Gruen, EJ Sachar, and reply of JM Davis, Sept, 1090
Rapid treatment of acute psychosis, WH Anderson, JC Kuehnle, DM Catanzano, Sept, 1076–1078
Rational treatment for an irrational disorder: what does the schizophrenic patient need? PRA May, Sept, 1008–1012
Recent developments in the drug treatment of schizophrenia, JM Davis, Feb, 208–214
Thioridazine and sexual dysfunction, J Kotin, DE Wilbert, D Verburg, SM Soldinger, Jan, 82–85
Thiothixene and the postpsychotic depressive syndrome (ltr to ed), VF Ognyanov, and reply of TH McGlashan, WT Carpenter Jr, July, 861–862

l-Alpha-Acetylmethadol (LAAM)

l-Alpha-acetylmethadol (LAAM): prognostic considerations, RB Resnick, L Orlin, G Geyer, E Schuyten-Resnick, RS Kestenbaum, AM Freedman, July, 418–819
Therapeutic effects of methadone and *l*-α-acetylmethadol, E Karp-Gelernter, L Wurmser, C Savage, Aug, 955–957

Lithium

A clarification (ltr to ed), DD Chisholm, and reply of JM Davis, July, 858
Cogwheel rigidity early in lithium therapy (ltr to ed), RD Bien, and reply of B Shopsin, S Gershon, Sept, 1093–1094
Combining lithium and neuroleptics (ltr to ed), JS Brust, and reply of B Shopsin, JG Small, JJ Kellams, V Milstein, JE Moore, Aug, 980–981
The effect of lithium on impulsive aggressive behavior in man, MH Sheard, JL Marini, CI Bridges, E Wagner, Dec, 1409–1413
Extrapyramidal side effects in lithium maintenance therapy, MH

Branchey, J Charles, GM Simpson, April, 444–445
A favorable response to lithium carbonate in a "schizo-affective" father and son, DE Reiser, AB Willett, July, 824–827
Lithium and affective disorders associated with organic brain impairment (ltr to ed), DB Mehta, Feb, 236
Lithium—depressant or antidepressant? (ltr to ed), M Ostow, Nov, 1349
Lithium and depression (ltr to ed), RO Friedel, Aug, 976
Lithium prophylaxis of depression in bipolar I, bipolar II, and unipolar patients, RR Fieve, T Kumbaraci, DL Dunner, Aug, 925–929
Lithium in schizophrenia (ltr to ed), A Taheri, Oct, 1208
Lithium in the treatment of depression, J Mendels, April, 373–378
Overview: maintenance therapy in psychiatry: II. Affective disorders, JM Davis, Jan, 1–13
Practicing what we preach (ltr to ed), RH Bridenbaugh, June, 717–718
On prophylaxis in unipolar affective disorder (ltr to ed), F Quitkin, A Rifkin, DF Klein, JM Davis, Sept, 1091–1092
Relationship between dosage and response to lithium prophylaxis in recurrent depression, RF Prien, EM Caffey Jr, May, 567–570
Treatment of excessive weight gain in patients taking lithium, GM Dempsey, DL Dunner, RR Fieve, T Farkas, J Wong, Sept, 1082–1084
The 24-hour lithium level as a prognosticator of dosage requirements: a 2-year follow-up study, TB Cooper, GM Simpson, April, 440–443

Methadone

Clinical depression among narcotic addicts maintained on methadone in the community, MM Weissman, F Slobetz, B Prusoff, M Mezritz, P Howard, Dec, 1434–1438
Digit-symbol performance in methadone-treated ex-heroin addicts, PW Appel, NB Gordon, Nov, 1337–1339
Therapeutic effects of methadone and *l*-α-acetylmethadol, E Karp-Gelernter, L Wurmser, C Savage, Aug, 955–957

Physostigmine

The reversal of tricyclic-overdosage-induced central anticholinergic syndrome by physostigmine, PC Holinger, HL Klawans, Sept, 1018–1023
Treatment of tricyclic intoxication, RA Munoz, Sept, 1085–1087

Propranolol

The treatment of pathological panic states with propranolol, JF Heiser, D DeFrancisco, Dec, 1389–1394

Sedatives

The concept of drug automatism, MI Good, Aug, 948–952

Stimulants

Cocaine, kindling, and psychosis, RM Post, RT Kopanda, June, 627–634
Coffee consumption among psychiatric inpatients, DK Winstead, Dec, 1447–1450
Failure of deanol in treating tardive dyskinesia (ltr to ed), D Mehta, S Mehta, P Mathew, Dec, 1467
A problem of methodology? (ltr to ed), AW Mariner, and reply of BD Garfinkel, CD Webster, L Sloman, March, 345–346
Treatment of tardive dyskinesia with deanol (ltr to ed), BB Kumar, Aug, 978

THC (Marijuana, Hashish)

The effect of marijuana on carbohydrate metabolism, MA Permutt, DW Goodwin, R Schwin, SY Hill, Feb, 220–222
Marijuana effects on simulated flying ability, DS Janowsky, MP Meacham, JD Blaine, M Schoor, LP Bozzetti, April, 384–388
Tracking difficulties and paranoid ideation during hashish and alcohol intoxication, FT Melges, Sept, 1024–1028

EATING DISORDERS

Diphenylhydantoin treatment of bulimia (ltr to ed), T Weiss, L Levitz, Sept, 1093
Hypothalamic tumor presenting as anorexia nervosa, GB Heron, DA Johnston, May, 580–582
Preciseness in diagnostic terminology (ltr to ed), H Bruch, Sept, 1093
Studies of superobesity: II. Psychiatric appraisal of jejuno-ileal bypass surgery, P Castelnuovo-Tedesco, D Schiebel, Jan, 26–31
The treatment of anorexia nervosa, AR Lucas, JW Duncan, V Piens, Sept, 1034–1038

ECT

ECT as maintenance therapy in schizophrenia (ltr to ed), G Asnis, AN Gabriel, July, 858–859
ECT in the treatment of mania: a controlled study, MS McCabe, June, 688–691
Portable electromyograph monitoring of unilateral ECT, JO Ives, LA Weaver, R Williams, Nov, 1340–1341

EDITORIALS

Editing circa 1976 (editorial), FJ Braceland, Jan, 76–79
An opportunity to stimulate self-evaluation and learning (editorial), SL Werkman, Feb, 215–216
Rape: "the ultimate violation of the self" (editorial), E Hilberman, April, 436–437

EDUCATION, MEDICAL

Consultation-liaison psychiatry: current responsibilities, WA Brown, EM Jacobson, March, 326–328
The psychiatrist in primary medical care training: a solution to the mind-body dichotomy? AM Lazerson, Aug, 964–966
Psychodynamics in medical education (ltr to ed), H Stein, and reply of W Johnson, April, 453–454
Sexual attitudes of hospital personnel: a model for continuing education, DJ Withersty, May, 573–575

EDUCATION, PSYCHIATRIC

Another approach to avoidance (ltr to ed), M Blumenfield, and reply of MK Goin, July, 851
Attitude of psychiatric residents toward patient requests, S Eisenthal, R Ferrell, A Lazare, Sept, 1079–1081
Attitudes of psychiatric residents toward payment of psychotherapy fees, BS Meyers, Dec, 1460–1462
Behavioral theory in psychiatric education (ltr to ed), OG Cameron, Aug, 977
Competency-based psychiatric education, HM Weinstein, ML Russell, Aug, 935–939
Continuing education or business? (ltr to ed), RJ Mearin, Jan, 102
Countertransference: a neglected subject in clinical supervision, MK Goin, F Kline, Jan, 41–44
Current trends in the training of family therapists, EW Beal, Feb, 137–141
The educational objectives of a psychiatric residency program, J Yager, RO Pasnau, Feb, 217–220

Experiences of psychiatry Board exam casualties: a survey report, MR Lipp, March, 279–283
The future of psychiatry and inpatient wards (ltr to ed), DE Raskin, Jan, 106
Is countertransference an appropriate issue in clinical supervision? (ltr to ed), UP Bhatt, and reply of MK Goin, June, 714–715
An opportunity to stimulate self-evaluation and learning (editorial), SL Werkman, Feb, 215–216
Product goals for residency programs (ltr to ed), PH Blachly, and reply of J Yager, RO Pasnau, Sept, 1088–1089
A program problem? (ltr to ed), K Solomon, and reply of J Yager, RO Pasnau, Sept, 1095
The psychiatric resident as an ex-officio community board member, A Beigel, R Bevan, J LaWall, J Orttung, D Westin, Oct, 1200–1202
The psychiatrist in primary medical care training: a solution to the mind-body dichotomy? AM Lazerson, Aug, 964–966
Psychotherapy fees and residency training, SA Pasternack, P Treigar, Sept, 1064–1066
The role of the chief resident: expectations and reality, JF Wilder, R Plutchik, HR Conte, March, 328–331
Some problems in learning to do "good psychotherapy," M Lakovics, July, 834–837
Student mental health services and departments of psychiatry, CB Reifler, R Babineau, Aug, 967–968
Training and accreditation for the treatment of sexual disorders, JK Meyer, April, 389–394
Use of the problem-oriented medical record in psychiatry: a survey of university-based residency training programs, EH Liston, June, 700–703
Who gets supervised? An extension of patient selection inequity, RW Burgoyne, S Santini, F Kline, FB Staples, Nov, 1313–1315

EEG

Neuropsychological and EEG disturbances in polydrug users, J Grant, LL Judd, Sept, 1039–1042
Self-reports versus sleep laboratory findings in 122 drug-free subjects with complaints of chronic insomnia, MA Carskadon, WC Dement, MM Mitler, C Guilleminault, VP Zarcone, R Spiegel, Dec, 1382–1388

EPIDEMIOLOGY

Clinical depression among narcotic addicts maintained on methadone in the community, MM Weissman, F Slobetz, B Prusoff, M Mezritz, P Howard, Dec, 1434–1438
The frequency of suicide attempts: a retrospective approach applied to college students, BL Mishara, AH Baker, TT Mishara, July, 841–844
Occurrence of psychiatric disorder in a county jail population, GE Swank, D Winer, Nov, 1331–1333
Presence and persistence of depressive symptoms in patient and community populations, TJ Craig, PA Van Natta, Dec, 1426–1429
Psychiatric disturbances of aged patients in skilled nursing homes, RB Teeter, FK Garetz, WR Miller, WF Heiland, Dec, 1430–1434
Psychiatric morbidity in a metropolitan county jail population, J Petrich, Dec, 1439–1444

EPILEPSY

Delinquency, psychomotor epileptic symptoms, and paranoid ideation: a triad, DO Lewis, Dec, 1395–1398
Psychiatric presentations of seizure disorders, J LaWall, March, 321–323
Psychiatric test assessment of patients with psychomotor epilepsy, EA Serafetinides, DG Cherlow, July, 844–847

ETHICS

Can psychiatry police itself effectively? The experience of one district branch, A Zitrin, H Klein, June, 653–656
The case for involuntary hospitalization of the mentally ill, P Chodoff, May, 496–501
Characteristics of "erotic" practitioners, SH Kardener, M Fuller, IN Mensh, Nov, 1324–1325
The legal implications of sexual activity between psychiatrist and patient, AA Stone, Oct, 1138–1141
More on free will (ltr to ed), V Siomopoulos, Jan, 104–105
Overview: ethical issues in contemporary psychiatry, F Redlich, FR Mollica, Feb, 125–136
Psychosurgery for political purposes (ltr to ed), PR Breggin, July, 864
Psychosurgery: some current observations, SA Shevitz, March, 266–270
Putting ethics into practice (ltr to ed), GA Rogers, and reply of F Redlich, RF Mollica, Aug, 978–979
A question of ethics (ltr to ed), anonymous, July, 851

EXTRAPYRAMIDAL SYMPTOMS

Amantadine versus trihexyphenidyl in the treatment of neuroleptic-induced parkinsonism, WE Fann, CR Lake, Aug, 940–943
Anticholinergic exacerbation of phenothiazine-induced extrapyramidal syndrome, M Alpert, F Diamond, EM Laski, Sept, 1073–1075
Catatonialike symptomatology and withdrawal dyskinesia, MI Good, Dec, 1454–1456
Cogwheel rigidity early in lithium therapy (ltr to ed), RD Bien, and reply of B Shopsin, S Gershon, Sept, 1093–1094
Computerized tomography in patients with tardive dyskinesia, AJ Gelenberg, May, 578–579
Diagnosis and treatment in a case of tardive dyskinesia (ltr to ed), RA Kuwik, MJ Steinhart, and reply of DE Casey, D Denney, March, 346–347
Extrapyramidal side effects in lithium maintenance therapy, MH Branchey, J Charles, GM Simpson, April, 444–445
Failure of deanol in treating tardive dyskinesia (ltr to ed), D Mehta, S Mehta, P Mathew, Dec, 1467
Low urinary dopamine and prediction of phenothiazine-induced parkinsonism: a preliminary report, TJ Crowley, CO Rutledge, MM Hoehn, MA Stallings, S Sundell, June, 703–706
Maintenance antipsychotic therapy: is the cure worse than the disease? G Gardos, J Cole, Jan, 32–36
Manganese in dyskinesias (ltr to ed), RA Kunin, Jan, 105
A medical student's experience with akathisia (ltr to ed), KS Kendler, April, 454–455
A methodological question (ltr to ed), AJ Gelenberg, MR Mandel, and reply of S Idzorek, July, 860–861
More on neuromuscular side effects of antipsychotics (ltr to ed), AJ Gelenberg, and reply of HR Barton, Sept, 1089–1090
Neuromuscular side effects of antipsychotic drugs (ltr to ed), HR Barton, Jan, 106–107
Treatment of tardive dyskinesia with deanol (ltr to ed), BB Kumar, Aug, 978

FAMILY PROCESSES AND FAMILY THERAPY

Adolescent parricide: a comparison with other adolescent murder: BF Corder, BC Ball, TM Haizlip, R Rollins, R Beaumont, Aug, 957–961
Brief versus standard hospitalization: the families, MI Herz, J Endicott, RL Spitzer, July, 795–801
Child custody contests in historical perspective, AP Derdeyn, Dec, 1369–1376
Current trends in the training of family therapists, EW Beal, Feb, 137–141

Early sex education in relationship to later coital and reproductive behavior: evidence from Jamaican women, EB Brody, F Ottey, J LaGranade, Aug, 969–972
The effects of the sealed record in adoption, AD Sorosky, A Baran, R Pannor, Aug, 900–904
Family and character change at Buffalo Creek, JL Titchener, FT Kapp, March, 295–299
The family in exile: Cuban expatriates in the United States, RD Rumbaut, RG Rumbaut, April, 395–399
The family and schizophrenia, D Reiss, Feb, 181–185
The fatal myth of death in the family, EM Pattison, June, 674–678
A general systems approach to severe family pathology, S Fleck, June, 669–673
Linguistic performance in vulnerable and autistic children and their mothers, SM Frank, DA Allen, L Stein, B Myers, Aug, 909–915
Loss of communality at Buffalo Creek, KT Erikson, March, 302–305
"Misleading" concepts in family therapy (ltr to ed), FM Sander, and reply of LR Robinson, March, 344–345
A new concept and finding in morbid jealousy, JP Docherty, J Ellis, June, 679–683
Overview: research on the psychology of women. II. Women in families, work, and psychotherapy, AM Seiden, Oct, 1111–1123
The role of neurosis in phylogenetic adaptation, with particular reference to early man, L Sloman, May, 543–547
Siblings as therapists: a behavioral approach, NB Miller, DP Cantwell, April, 447–450
Training community-based paraprofessionals as behavior therapists with families of alcohol-abusing adolescents, JD Teicher, RD Sinay, JS Stumphauzer, July, 847–850
Treatment for the parents of feminine boys, LE Newman, June, 683–687

FEES

Attitudes of psychiatric residents toward payment of psychotherapy fees, BS Meyers, Dec, 1460–1462
Free psychotherapy: an inquiry into resistance, JL Nash, JO Cavenar, Sept, 1066–1069
Patient responsibility and free psychotherapy (ltr to ed), J Paris, Dec, 1471–1472
Psychotherapy fees and residency training, SA Pasternack, P Treiger, Sept, 1064–1066

FOLLOW-UP STUDIES

Effects of peer review on outpatient psychotherapy: therapist and patient follow-up survey, LL Luft, LM Sampson, D Newman, Aug, 891–895
Evolution of behavior disorders into adolescence, A Thomas, S Chess, May, 539–542
Follow-up of depressed women after maintenance treatment, MM Weissman, SV Kasl, GL Klerman, July, 757–760
A follow-up of 78 patients with Gilles de la Tourette's syndrome, RD Bruun, AK Shapiro, E Shapiro, R Sweet, H Wayne, GE Solomon, Aug, 944–947
Psychiatric effects of prolonged Asian captivity: a two-year follow-up, RCW Hall, PT Malone, July, 786–790
A query on follow-up results (ltr to ed), RB Davis, and reply of JS Bockoven, Sept, 1089
Short versus long hospitalization: a prospective controlled study. IV. One-year follow-up results for schizophrenic patients, ID Glick, WA Hargreaves, J Drues, JA Showstack, May, 509–514
Short versus long hospitalization: a prospective controlled study. V. One-year follow-up results for nonschizophrenic patients, ID Glick, WA Hargreaves, J Drues, JA Showstack, May, 515–517
The significance of childhood neurosis for adult mental health: a follow-up study, S Waldron Jr, May, 532–538
A symposium: follow-studies of community care, M Greenblatt, RD Budson (eds), Aug, 916–921

FOREIGN MEDICAL GRADUATES

Certification for foreign medical graduates (ltr to ed), AK Nafees, Feb, 233–234

FORENSIC PSYCHIATRY

Assessment of sociolegal judgment of offenders, MS Cerino, AJ Dy, Aug, 973–975
Child custody contests in historical perspective, AP Derdeyn, Dec, 1369–1376
On dangerousness and involuntary hospitalization (ltrs to ed), HJ Fulton; IN Hassenfeld, and reply of P Chodoff, Oct, 1206–1207
Forensic psychiatry: profiles of two types of sex offenders, FA Henn, M Herjanic, RH Vanderpearl, June, 694–696
From chaos to responsibility, GM Stern, March, 300–301
The legal implications of sexual activity between psychiatrist and patient, AA Stone, Oct, 1138–1141
A modest proposal (ltr to ed), DA Sargent, June, 713
Overview: ethical issues in contemporary psychiatry, F Redlich RF Mollica, Feb, 125–136
Parens patriae and psychiatry (ltr to ed), L Coleman, and reply of MA Peszke, Feb, 234–235
Practicing what we preach (ltr to ed), RH Bridenbaugh, June, 717–718
A problem of commitment (ltr to ed), FL Willoughby, Jan, 103–104
The psychiatrist as expert witness (ltr to ed), B Rollins, Aug, 976–977
The psychotherapist and informed consent, JO Noll, Dec, 1451–1453
A review of major implications of the *O'Connor v. Donaldson* decision, LE Kopolow, April, 379–383

FREUD

Pulling a white-coated tale (ltr to ed), DA Sargent, and reply of RJ Blank, Sept, 1096–1097
A white-coated tale (ltr to ed), RJ Blank, March, 347–348

GENETIC STUDIES

Albinism and schizophreniform psychosis: a pedigree study, M Baron, Sept, 1070–1073
Estimating the genetic contribution to schizophrenia, SW Matthysse, KK Kidd, Feb, 185–191
A reconsideration of the Kety and associates study of genetic factors in the transmission of schizophrenia, LS Benjamin, Oct, 1129–1133
The role of neurosis in phylogenetic adaptation, with particular reference to early man, L Sloman, May, 543–547
Studies designed to disentangle genetic and environmental variables in schizophrenia: some epistemological questions and answers, SS Kety, Oct, 1134–1137
Triple mosaicism of X chromosomes in bipolar affective disorder (ltr to ed), Y-T Kusumi, June, 719

GERIATRIC PSYCHIATRY

Mental health services and the elderly: needs and options, GD Cohen, Jan, 65–68
Psychiatric disturbances of aged patients in skilled nursing homes, RB Teeter, FK Garetz, WR Miller, WF Heiland, Dec, 1430–1434
Request for information (ltr to ed), C Lieberman, Dec, 1467
Services for the aged in community mental health centers, RD Patterson, March, 271–273

GILLES DE LA TOURETTE'S SYNDROME

A follow-up of 78 patients with Gilles de la Tourette's syndrome, RD Bruun, AK Shapiro, E Shapiro, R Sweet, H Wayne, GE Solomon, Aug, 944–947

GROUP THERAPY AND GROUP PROCESSES

Another leaderless group (ltr to ed), M Blaustein, April, 452–453
Effect of drug ritual changes on schizophrenic patients, RW Burgoyne, March, 284–289
Marijuana and hostility in a small-group setting, C Salzman, BA Van der Kolk, RI Shader, Sept, 1029–1033
Patients' expectations of therapeutic improvement and their outcome, S Bloch, G Bond, B Qualls, I Yalom, E Zimmerman, Dec, 1457–1450
Patients' perceptions of the therapeutic relationship and group therapy outcome, AS Gurman, JP Gustafson, Nov, 1290–1294
"Something more" (ltr to ed), C Folkins, J Spensley, F Pepitone-Rockwell, and reply of WR Hunt, A Issacharoff, July, 854–855
Therapy groups for women, CS Wolman, March, 274–278

HALLUCINATIONS

They hear music (ltr to ed), WL Clovis, Sept, 1096

HISTORY

A Bicentennial address: Benjamin Rush and those who came after him, FJ Braceland, Nov, 1251–1258
Child custody contests in historical perspective, AP Derdeyn, Dec, 1368–1375
1976 anniversaries, G Mora, Dec, 1419–1425
Pulling a white-coated tale (ltr to ed), DA Sargent, and reply of RJ Blank, Sept, 1096–1097
A white-coated tale (ltr to ed), RJ Blank, March, 347–348

HORMONES

Negative effects of melatonin on depression, JS Carman, RM Post, R Buswell, FK Goodwin, Oct, 1181–1186
Thyrotropin-releasing hormone: differential antidepressant and endocrinological effects, FW Furlong, GM Brown, MF Beeching, Oct, 1187–1190

HOSPITALS AND HOSPITALIZATION

Brief versus standard hospitalization: the families, MI Herz, J Endicott, RL Spitzer, July, 795–801
The case for involuntary hospitalization of the mentally ill, P Chodoff, May, 496–501
Clarification (ltr to ed), MF Heiman, MA Johnson, and reply of M Greenblatt, E Glazier, June, 718–719
A fair comparison? (ltr to ed), HL Freeman, and reply of JS Bockoven, HC Solomon, July, 856–857
A five-year study of brief hospitalization, M Swartzburg, A Schwartz, Aug, 922–924
Joint admission as a treatment modality for problem drinkers: a case report, TJ Paolino, BS McCrady, Feb, 222–224
Limitations of brief hospital treatment, S Reibel, MI Herz, May, 518–521
Overview: psychiatric sequelae to multiple trauma, N Schnaper, RA Cowley, Aug, 883–890
Patient and staff reactions to a strike by essential hospital employees, GL Hogben, R Shulman, Dec, 1464–1465
Sexual attitudes of hospital personnel: a model for continuing education, DJ Withersty, May, 573–575
Short versus long hospitalization: a prospective controlled study. IV. One-year follow-up results for schizophrenic patients, ID Glick, WA Hargreaves, J Drues, JA Showstack, May, 509–514
Short versus long hospitalization: a prospective controlled study. V. One-year follow-up results for nonschizophrenic patients, ID Glick, WA Hargreaves, J Drues, JA Showstack, May, 515–517
Trends in hospital versus community treatment of mental illness: a Texas example, JL Claghorn, GW McBee, L Roberts, Nov, 1310–1312

HOSTILITY

Marijuana and hostility in a small-group setting, C Salzman, BA Van der Kolk, RI Shader, Sept, 1029–1033

HYPERACTIVITY

Focusing on television (ltr to ed), MP Dumont, April, 457
Lead and hyperactivity. Behavioral response to chelation: a pilot study, OJ David, SP Hoffman, J Sverd, J Clark, K Voeller, Oct, 1155–1158

HYPOGLYCEMIA

Neuropsychiatric symptoms in hypoglycemia (ltr to ed), J Wilder, June, 720
A psychiatric study of patients referred with a diagnosis of hypoglycemia, CV Ford, GA Bray, RS Swerdloff, March, 290–294

HYSTERIA

An interpersonal approach to hysteria, D Celani, Dec, 1414–1418
Methodology and personality in Briquet's syndrome: a reappraisal, MJ Kaminsky, PR Slavney, Jan, 85–88
The semantics of hysteria continued (ltr to ed), EL Margetts, Jan, 103; correction, April, 457

INSURANCE

Current issues in national insurance for mental health services, SH Nelson, July, 761–764
Insuring psychiatrists (ltrs to ed), G Bajor; B Lipton, and reply of CL Trent, June, 713–714
Mental health services in the public and private sectors, LM Koran, Sept, 1052–1057
Milieu therapy: toward a definition for reimbursement, LE Kopolow, GD Cohen, Sept, 1060–1063
Peer review and PSRO: an update, FW Sullivan, Jan, 51–55
Should intensive psychotherapy be insured? (ltrs to ed), TE Bittker; WL Allan, and reply of SS Sharfstein, HL Magnas, June, 715–717
Utilization of prepaid services by patients with psychiatric diagnoses, DT Fullerton, FN Lohrenz, GR Nyca, Sep , 1057–1060

INTERDISCIPLINARY RELATIONS

Craft versus profession in alcoholism treatment (ltrs to ed), M Galanter; R Peele; EM Scott, and reply of M Kalb, MS Propper, Nov, 1345–1346

The future of alcohology: craft or science? M Kalb, MS Propper, June, 641–645
More "craft versus science" (ltr to ed), TT Flynn, and reply of MS Propper, M Kalb, Dec, 1467–1468

JEALOUSY

Etiology and differential diagnosis of the morbid jealousies (ltr to ed), CG Dunn, and reply of JP Docherty, Nov, 1346–1347
A new concept and finding in morbid jealousy, JP Docherty, J Ellis, June, 679–683

JUNG

On Jungian psychology (ltr to ed), HA Wilmer, April, 452

LANGUAGE AND LANGUAGE DISTURBANCES

The effect of haloperidol on stuttering, PB Rosenberger, JA Wheelden, M Kalotkin, March, 331–334
Linguistic performance in vulnerable and autistic children and their mothers, SM Frank, DA Allen, L Stein, B Myers, Aug, 909–915
On sexism in the language (ltr to ed), K Solomon, Dec, 1466–1467
Strategies and risks in psychotherapy with bilingual patients: the phenomenon of language independence, LR Marcos, M Alpert, Nov, 1275–1278

LAW SUITS

From chaos to responsibility, GM Stern, March, 300–301
A review of major implications of the *O'Connor v. Donaldson* decision, LE Kopolow, April, 379–383

LITERATURE, PSYCHIATRIC

Editorial practices of psychiatric and related journals: implications for women, EP Benedek, Jan, 89–92

MARRIAGE AND MARITAL THERAPY

Behavior therapy and sex therapy, JP Brady, Aug, 896–899
The cessation of marital intercourse, JN Edwards, A Booth, Nov, 1333–1336
Marital therapy when one spouse has a primary affective disorder, BL Greene, N Lustig, RR Lee, July, 827–830
A new concept and finding in morbid jealousy, JP Docherty, J Ellis, June, 679–683
Profiles of couples seeking sex therapy and marital therapy, E Frank, C Anderson, DJ Kupfer, May, 559–562
The role of sex therapy in marital therapy, CJ Sager, May 555–559
A therapeutic example (ltr to ed), RC Evans, Nov, 1346

MEDITATION

Self-induced depersonalization syndrome, RB Kennedy Jr, Nov, 1326–1328

MENTAL HEALTH, CURRENT ISSUES

A Bicentennial address: Benjamin Rush and those who came after him, FJ Braceland, Nov, 1251–1258
Can program evaluation be saved from its enthusiasts? J Zusman, Nov, 1300–1305
The case for involuntary hospitalization of the mentally ill, P Chodoff, May, 496–501
Community mental health center legislation: flight of the phoenix, FM Ochberg, Jan, 56–61
Corporate inhumanity (ltr to ed), DB Moss, and reply of JL Titchener, FT Kapp, Sept, 1094–1095
Crime and violence among mental patients, A Zitrin, AS Hardesty, EI Burdock, AK Drossman, Feb, 142–149
Current issues in national insurance for mental health services, SH Nelson, July, 761–764
Economics and ethics (ltr to ed), RL Goldstein, and reply of MH Keeler, RL McCurdy, Jan, 102
Is dying being worked to death? RJ Cohen, May, 575–577
Is psychiatry doing the job? (ltr to ed), IM Rosen, and reply of BS Brown, Nov, 1347–1348
The life of psychiatry, BS Brown, May, 489–495
Mental health services in the public and private sectors, LM Koran, Sept, 1052–1057
Overview: ethical issues in contemporary psychiatry, F Redlich, RF Mollica, Feb, 125–136
Patient privacy and confidentiality at mental health centers, JO Noll, MJ Hanlon, Nov, 1286–1289
Position statement on mental health representation in governance and staffing of health systems agencies (off acts), May, 601–602
Presidential address: psychiatry 1976—the continuing revolution, J Marmor, July, 739–745; correction, Sept, 1097
Psychosurgery: some current observations, SA Shevitz, March, 266–270
Quality-of-care standards and professional norms, HC Schulberg, Sept, 1047–1051
A review of major implications of the *O'Connor v. Donaldson* decision, LE Kopolow, April 379–383
A television stereotype (ltr to ed), DA Dansak, April, 457

MILIEU THERAPY

Milieu therapy: toward a definition for reimbursement, LE Kopolow, GD Cohen, Sept, 1060–1063

MILITARY PSYCHIATRY

Confidentiality in military psychiatry (ltr to ed), TJ Wilf, July, 864
Psychiatric effects of prolonged Asian captivity: a two-year-follow-up, RCW Hall, PT Malone, July, 786–790
The why of fragging, TC Bond, Nov, 1328–1331

MINIMAL BRAIN DYSFUNCTION

The identification and treatment of adult brain dysfunction, HB Mann, SI Greenspan, Sept, 1013–1017
A problem of methodology? (ltr to ed), AW Mariner, and reply of BD Garfinkel, CD Webster, L Sloman, March, 345–346

MINORITY GROUPS

Correlates of patient attendance in an inner-city mental health clinic, TJ Craig, CL Huffine, Jan, 61–65
Editorial practices of psychiatric and related journals: implications for women, EP Benedek, Jan, 89–92
Position statement on administration of psychiatric facilities (off acts), May, 604
Position statement on desegregation of hospitals for the mentally ill and retarded (off acts), May, 603

Position statement on the training of minority psychiatrists (off acts, May, 605
Psychiatry and folk healing: a dichotomy? P Ruiz, J Langrod, Jan, 95–97

NEUROPSYCHIATRY

Carbon monoxide encephalopathy: need for appropriate treatment, R Ginsburg, J Romano, March 317–320
Neuropsychological and EEG disturbances in polydrug users, I Grant, LL Judd, Sept, 1039–1042
Personality disorder and parietal lobe dysfunction, PC Horton, July, 732–785
Problems in the differential diagnosis of narcolepsy versus schizophrenia, B Shapiro, H Spitz, Nov, 1321–1323
Psychiatric presentations of seizure disorders, J LaWall, March, 321–323
Routine skull films in hospitalized psychiatric patients, JF Delaney, Jan, 93–95
Subtle neuropsychiatric sequelae of carbon monoxide intoxication: two case reports, JW Jefferson, Aug, 961–964
Viral encephalopathy mimicking functional psychosis, LG Wilson, Feb, 165–170
Viral encephalopathy and psychosis (ltr to ed), RM Stewart, RJ Baldessarini. June, 717

NEUROSIS

Diabetes insipidus and obsessional neurosis (ltr to ed), R Barton, Feb, 235–236
Family and character change at Buffalo Creek, JL Titchener, FT Kapp, March, 295–299
Natural selection and neurosis (ltr to ed), DH Ingram, and reply of L Sloman, Nov, 1351–1352
The role of neurosis in phylogenetic adaptation, with particular reference to early man, L Sloman, May, 543–547
The significance of childhood neurosis for adult mental health: a follow-up study, S Waldron Jr, May, 532–538

NOMENCLATURE, PSYCHIATRIC

Clarifying diagnostic terminology (ltr to ed), LW Coulter, Jan, 104
Current diagnostic concepts in schizophrenia, WT Carpenter Jr, Feb, 172–177
Preciseness in diagnostic terminology (ltr to ed), H Bruch, Sept, 1093
In a semantic mood (ltr to ed), RH Isaac, and reply of R Ketai, June, 720
The semantics of hysteria continued (ltr to ed), EL Margetts, Jan, 103; correction, April, 457
Semantics and psychiatry (ltr to ed), FP Kosbab, and reply of R Ketai, March, 347
"Sociopathy" and child psychiatry (ltr to ed), AF Kinzel, and reply of DO Lewis, DA Balla, Jan, 102–103

OBESITY

Behavioral changes following surgery for obesity, MJ Mills, AJ Stunkard, May, 527–531
Studies of superobesity: II. Psychiatric appraisal of jejuno-ileal bypass surgery, P Castelnuovo-Tedesco, D Schiebel, Jan, 26–31
Treatment of excessive weight gain in patients taking lithium, MG Dempsey, DL Dunner, RR Fieve, T Farkas, J Wong, Sept, 1082–1084

OBITUARIES

Benjamin Harris Balser, 1905–1975 (in mem), RS Mumford, Jan, 101
George Herbert Stevenson, 1894–1976 (in mem), JD Griffin, Nov, 1342–1344
Malcolm J Farrell, 1906–1975, WE Barton, March, 342–343

ORGANIC BRAIN SYNDROME

Carbon monoxide encephalopathy: need for appropriate treatment, R Ginsberg, J Romano, March, 317–320
Diagnosis and treatment after CO poisoning, (ltr to ed), RA Remick, Aug 978
Encephalopathy and psychiatric diagnosis (ltrs to ed), CE Wells; R Malcolm, and reply of LG Wilson, July, 859–860
The identification and treatment of adult brain dysfunction, HB Mann, SI Greenspan, Sept, 1013–1017
Lithium and affective disorders associated with organic brain impairment (ltr to ed), DB Mehta, Feb, 236
Organic brain dysfunction and personality disorder (ltrs to ed), DP Rohmann-Moore; ER Erard, and reply of PC Horton, Dec, 1469–1471
Psychiatric presentations of seizure disorders, J LaWall, March, 321–323
Psychiatric test assessment of patients with psychomotor epilepsy, EA Serafetinides, DG Cherlow, July, 844–847
A request (ltr to ed), FM James, Sept, 1091
Routine skull films in hospitalized psychiatric patients, JF Delaney, Jan, 93–95
Viral encephalopathy and psychosis (ltr to ed), RM Stewart, RJ Baldessarini, June, 717
Viral encephalopathy mimicking functional psychosis, LG Wilson, Feb, 165–170

OUTPATIENT TREATMENT

Brief versus standard hospitalization: the families, MI Herz, J Endicott, RL Spitzer, July, 795–801
A description and evaluation of an outpatient intensive psychotherapy center, W Swenson, HR Martin, Sept, 1043–1046
Effects of peer review on outpatient psychotherapy: therapist and patient follow-up survey, LL Luft, LM Sampson, D Newman, Aug, 891–895
A five-year study of brief hospitalization, M Swartzburg, A Schwartz, Aug, 922–924
Trends in hospital versus community treatment of mental illness: a Texas example, JL Claghorn, GW McBee, L Roberts, Nov, 1310–1312

OVERVIEW ARTICLES

Overview: ethical issues in contemporary psychiatry, F Redlich, RF Mollica, Feb, 125–136
Overview: maintenance therapy in psychiatry: II. Affective disorders, JM Davis, Jan, 1–13
Overview: psychiatric sequelae to multiple trauma, N Schnaper, RA Cowley, Aug, 883–890
Overview: research on the psychology of women. I Gender differences and sexual and reproductive life, AM Seiden, Sept, 995–1007
Overview: research on the psychology of women. II. Women in families, work, and psychotherapy, AM Seiden, Oct, 1111–1123
Overview: research on the psychology of women. II. Women in families, work, and psychotherapy, AM Seiden, Oct, 1111–1123
The syndrome of autism: a critical review, EM Ornitz, ER Ritvo, June, 609–621

PAIN

Atypical facial pain as a defense against psychosis, JF Delaney, Oct, 1151–1154
The psychiatrist and the pain clinic, I Pilowsky, July, 752–756

PARANOIA

Delinquency, psychomotor epileptic symptoms, and paranoid ideation: a triad. DO Lewis, Dec, 1395–1398
Tracking difficulties and paranoid ideation during hashish and alcohol intoxication, FT Melges, Sept, 1024–1028

PATIENT RIGHTS

The case for involuntary hospitalization of the mentally ill, P Chodoff, May, 496–501
On dangerousness and involuntary hospitalization (ltrs to ed), HJ Fulton; IN Hassenfeld, and reply of P Chodoff, Oct, 1206–1207
Overview: ethical issues in contemporary psychiatry: F Redlich, RF Mollica, Feb, 125–136
Patient privacy and confidentiality at mental health centers, JO Noll, MJ Hanlon, Nov, 1286–1289
The psychotherapist and informed consent, JO Noll, Dec, 1451–1453
Putting ethics into practice (ltr to ed), GA Rogers, and reply of F Redlich, RF Mollica, Aug, 978–979
A review of major implications of the *O'Connor v. Donaldson* decision, LE Kopolow, April, 379–383

PATIENT-THERAPIST RELATIONSHIP

Alcohol and drug abuse consultation in the general hospital: a systems approach, M Galanter, TB Karasu, JF Wilder, Aug, 930–934
Assault on the therapist, RM Whitman, BB Armao, OB Dent, April, 426–429
Assaults on psychiatrists by patients, DJ Madden, JR Lion, MW Penna, April, 422–425
Attitude of psychiatric residents toward patient requests, S Eisenthal, R Ferrell, A Lazare, Sept, 1079–1081
Countertransference: a neglected subject in clinical supervision, MK Goin, F Kline, Jan, 41–44
Cultural perspectives on the impact of women's changing roles on psychiatry, V Abernethy, June, 657–661
Effects of peer review on outpatient psychotherapy: therapist and patient follow-up survey, LL Luft, LM Sampson, D Newman, Aug, 891–895
Inspiration of psychotherapists by patients, E Messner, Dec, 1462–1463
The legal implications of sexual activity between psychiatrist and patient, AA Stone, Oct, 1138–1141
Management of interpersonal issues in systematic desensitization, DL Braff, M Raskin, D Geisinger, July, 791–794
Patients' perceptions of the therapeutic relationship and group therapy outcome, AS Gurman, JP Gustafson, Nov, 1290–1294
Postpsychotic state, convalescent environment, and therapeutic relationship in schizophrenic outcome, L Kayton, J Beck, SD Koh, Nov, 1269–1274
Principles of the new sex therapy, WH Masters, VE Johnson, May, 548–554
Prognostic correlates of psychotherapy in psychiatric outpatients, AK Shapiro, E Struening, E Shapiro, H Barten, July, 802–808
Sex bias in psychotherapy: a failure to confirm, SI Abramowitz, HB Roback, JM Schwartz, A Yasuna, CV Abramowitz, B Gomes, June, 706–709
Strategies and risks in psychotherapy with bilingual patients: the phenomenon of language independence, LR Marcos, M Alpert, Nov, 1275–1278

PEER REVIEW

Can program evaluation be saved from its enthusiasts? J Zusman, Nov, 1300–1305
Can psychiatry police itself effectively? The experience of one district branch, A Zitrin, H Klein, June, 653–656
Current issues in national insurance for mental health services, SH Nelson, July, 761–764
Effects of peer review on outpatient psychotherapy: therapist and patient follow-up survey, LL Luft, LM Sampson, D Newman, Aug, 891–895
Peer review of prescribing patterns in a CMHC, H Diamond, R Tislow, T Snyder Jr, K Rickels, June, 697–699
Peer review and PSRO: an update, FW Sullivan, Jan, 51–55
Quality-of-care standards and professional norms, HC Schulberg, Sept, 1047–1051

PERCEPTION

Tracking difficulties and paranoid ideation during alcohol and hashish intoxication, FT Melges, Sept, 1024–1028

PERSONALITY

The broad role of ego functions assessment, L Bellak, M Sheehy, Nov, 1259–1264
An interpersonal approach to hysteria, D Celani, Dec, 1414–1418
Methodology and personality in Briquet's syndrome: a reappraisal, MJ Kaminsky, PR Slavney, Jan, 85–88
Psychiatric aspects of dwarfism, JS Brust, CV Ford, DL Rimoin, Feb, 160–164

PERSONALITY DISORDER

Chronic hashish use and mental disorder, C Stefanis, A Liakos, J Boulougouris, M Fink, AM Freedman, Feb, 225–227
Organic brain dysfunction and personality disorder (ltrs to ed), DP Rohmann-Moore; RE Erard, and reply of PC Horton, Dec, 1469–1471
Personality disorder and parietal lobe dysfunction, PC Horton, July, 782–785
The psychological treatment of personality disorder, PC Horton, March, 262–265
Short versus long hospitalization: a prospective controlled study. V. One-year follow-up results for nonschizophrenic patients, ID Glick, WA Hargreaves, J Drues, JA Showstack, May, 515–517

PHOBIAS

The current status of behavioral psychotherapy: theory and practice, IM Marks, March, 253–261
The treatment of pathological panic states with propranolol, JF Heiser, D DeFrancisco, Dec, 1389–1394

PHYSICAL ILLNESS

Behavioral changes following surgery for obesity, MJ Mills, AJ Stunkard, May, 527–531
Behavioral characteristics of children with chronic nonspecific diarrhea, EH Wender, FB Palmer, JJ Herbst, PH Wender, Jan, 20–25
Cancer, emotions, and mental illness: the present state of understanding, FG Surawicz, DR Brightwell, WD Weitzel, E Othmer, Nov, 1306–1309

Diabetes insipidus and obsessional neurosis (ltr to ed), R Barton, Feb, 235–236
Hypothalamic tumor presenting as anorexia nervosa, GB Heron, DA Johnston, May, 580–582
Overview: psychiatric sequelae to multiple trauma, N Schnaper, RA Cowley, Aug, 883–890
Peer counseling in a general hospital, FG Guggenheim, S O'Hara, Oct, 1197–1199
Psychiatric aspects of dwarfism, JS Brust, CV Ford, DL Rimoin, Feb, 160–164
The psychiatrist and the pain clinic, I Pilowsky, July, 752–756

PHYSICIANS

The alcoholic physician: a survey, L Bissell, RW Jones, Oct, 1142–1146
Characteristics of "erotic" practitioners, SH Kardener, M Fuller, IM Mensh, Nov, 1324–1325
Physicians' erotic and nonerotic physical involvement with patients, JA Perry, July, 838–840

POLYDIPSIA

A theory on "psychogenic polydipsia" (ltr to ed), A Kubacki, July, 853–854

POSITION STATEMENTS

Position statement on administration of psychiatric facilities (off acts), May, 604
Position statement on desegregation of hospitals for the mentally ill and retarded (off acts), May, 603
Position statement on mental health representation in governance and staffing of health systems agencies (off acts), May, 601–602
Position statement of the quality of life (off acts), May, 603
Position statement on the training of minority psychiatrists (off acts), May, 605

POSTTRAUMATIC SYNDROME

Children of disaster: clinical observations at Buffalo Creek, CJ Newman, March, 306–312
Discussion of the Buffalo Creek disaster: the course of psychic trauma, L Rangell, March, 313–316
Family and character change at Buffalo Creek, JL Titchener, FT Kapp, March, 295–299
From chaos to responsibility, GM Stern, March, 300–301
Overview: psychiatric sequelae to multiple trauma, N Schnaper, RA Cowley, Aug, 883–890
"Postmanic traumatic neurosis" (ltr to ed), R Benson, and reply of J Kotin, July, 862–863
Psychiatric effects of prolonged Asian captivity: a two-year follow-up, RCW Hall, PT Malone, July, 786–790

PREDICTION OF OUTCOME, PROGNOSIS

Cluster analysis profiles of suicide attempters, A Kiev, Feb, 150–153
EEG sleep changes as predictors in depression, DJ Kupfer, FG Foster, L Reich, KS Thompson, B Weiss, June, 622–626
Effects of legal pressure on prognosis for treatment of drug dependence, RJ Harford, JC Ungerer, JK Kinsella, Dec, 1399–1404
An investigation of the postpsychotic depressive syndrome, TH McGlashan, WT Carpenter Jr, Jan, 14–19
Patients' expectations of therapeutic improvement and their outcomes, S Bloch, G Bond, B Qualls, I Yalom E Zimmerman, Dec, 1457–1460
Postpsychotic state, convalescent environment, and therapeutic relationship in schizophrenic outcome, L Kayton, J Beck, SD Koh, Nov, 1269–1274
Prognostic correlates of psychotherapy in psychiatric outpatients, AK Shapiro, E Struening, E Shapiro, H Barten July, 802–808
Red blood cell catechol *O*-methyltransferase and response to imipramine in unipolar depressive women, JRT Davidson, MN McLeod, HL White, D Raft, Aug, 952–955
REM sleep and adaptation of psychiatric patients: an application of sleep studies, R Greenberg, CA Pearlman, Oct, 1147–1150

PREGNANCY

Early sex education in relationship to later coital and reproductive behavior: evidence from Jamaican women, EB Brody, F Ottey, J LaGranade, Aug, 969–972

PREVENTION

Cluster analysis profiles of suicide attempters, A Kiev, Feb, 150–153
Male transsexuals in the homosexual subculture, EM Levine, Nov, 1318–1321
The need for insect sting kits (ltr to ed), CA Frazier, March, 346
"Primary" prevention? (ltr to ed), V Lentini, April, 452
On prophylaxis in unipolar affective disorder (ltr to ed), F Quitkin, A Rifkin, DF Klein, JM Davis, Sept, 1091–1092
We help each other: primary prevention for the widowed, WF McCourt, RD Barnett, J Brennen, A Becker, Jan, 98–100

PRISON AND PRISONERS

Assessment of sociolegal judgment of offenders, MS Cerino, AJ Dy, Aug, 973–975
Breaking into the prison: conducting a medical research project, JS Rubin, Feb, 230–232
Occurrence of psychiatric disorder in a county jail population, GE Swank, D Winer, Nov, 1331–1333
Psychiatric effects of prolonged Asian captivity: a two-year follow-up, RCW Hall, PT Malone, July, 786–790
Psychiatric morbidity in a metropolitan county jail population, J Petrich, Dec, 1439–1444

PRIVATE PRACTICE

Mental health services in the public and private sectors, LM Koran, Sept, 1052–1057
Recent information on private practice (ltr to ed), SS Sharfstein, ID Goldberg, Jan, 104

PSYCHIATRISTS

A Bicentennial address: Benjamin Rush and those who came after him, FJ Braceland, Nov, 1251–1258
Impact of a district branch task force on women, E Hilberman, M Gispert, J Harper, Oct, 1159–1164
The life of psychiatry, BS Brown, May, 489–495
Psychiatrist-wife-mother: some aspects of role integration, M Scher, E Benedek, A Candy, K Carey, J Mules, B Sachs, July, 830–834
Women in psychiatry: a review, NA Roeske, April, 365–372

PSYCHIATRY, CRITICISM OF

Can psychiatry police itself effectively? The experience of one district branch, A Zitrin, H Klein, June, 653–656
Editorial practices of psychiatric and related journals: implications for women, EP Benedek, Jan, 89–92
A question of ethics (ltr to ed), anonymous, July, 851

PSYCHIATRY, DEFINITION AND ROLE

A Bicentennial address: Benjamin Rush and those who came after him, FJ Braceland, Nov, 1251–1258
Cultural perspectives on the impact of women's changing roles on psychiatry, V Abernethy, June, 657–661
The educational objectives of a psychiatric residency program, J Yager, RO Pasnau, Feb, 217–220
The future of alcohology: craft or science? M Kalb, MS Propper, June, 641–645
The life of psychiatry, BS Brown, May, 489–495
Overview: ethical issues in contemporary psychiatry, F Redlich, RF Mollica, Feb, 125–136
Parens patriae and psychiatry (ltr to ed), L Coleman, and reply of MA Peszke, Feb, 234–235
Polarization or specialization? (ltr to ed), AE Pastor, Nov, 1350
Presidential address: psychiatry 1976—the continuing revolution, J Marmor, July, 739–745; correction, Sept, 1097
The psychiatrist as primary care physician (ltr to ed), JJ Karlavage, Jan, 106
The psychiatrist in primary medical care training: a solution to the mind-body dichotomy? AM Lazerson, Aug, 964–966
Quality-of-care standards and professional norms, HC Schulberg, Sept, 1047–1051
Response to the Presidential address, RW Gibson, July, 746–474
Women in psychiatry: a review, NA Roeske, April, 365–372

PSYCHOANALYSIS

The broad role of ego functions assessment, L Bellak, M Sheehy, Nov, 1259–1264
Discussion of the Buffalo Creek disaster: the course of psychic trauma, L Rangell, March, 313–316
On Jungian psychology (ltr to ed), HA Wilmer, April, 452
Personality disorder and parietal lobe dysfunction, PC Horton, July, 782–785
The psychological treatment of personality disorder, PC Horton, March, 262–265

PSYCHOSOMATIC MEDICINE

Atypical facial pain as a defense against psychosis, JF Delaney, Oct, 1151–1154
Cancer, emotions, and mental illness: the present state of understanding, FG Surawicz, DR Brightwell, WD Weitzel, E Othmer, Nov, 1306–1309
A psychiatric study of patients referred with a diagnosis of hypoglycemia, CV Ford, GA Bray, RS Swerdloff, March, 290–294
The psychiatrist and the pain clinic, I Pilowsky, July, 752–756
Studies of adoptees from psychiatrically disturbed biological parents: III. Medical symptoms and illnesses in childhood and adolescence, RJ Cadoret, L Cunningham, R Loftus, J Edwards, Nov, 1316–1318

PSYCHOSIS

Atypical facial pain as a defense against psychosis, JF Delaney, Oct, 1151–1154
Clinical response and plasma levels: effect of dose, dosage schedules, and drug interactions on plasma chlorpromazine levels, L Rivera-Calimlim, H Nasrallah, J Strauss, L Lasagna, June, 646–652
Cocaine, kindling, and psychosis, RM Post, RT Kopanda, June, 627–634
Diazepam treatment of socially isolated monkeys, AB Noble, WT McKinney Jr, C Mohr, E Moran, Oct, 1165–1170
ECT in the treatment of mania: a controlled study, MS McCabe, June, 688–691
Psychosis, thought disorder, and regression, NC Andreasen, PS Powers, May, 522–526
Rapid treatment of acute psychosis, WH Anderson, JC Kuehnle, DM Catanzano, Sept, 1076–1078
In search of the true amok: amok as viewed within the Malay culture, JE Carr, EK Tan, Nov, 1295–1299
Thiothixene and the postpsychotic depressive syndrome (ltr to ed), VF Ognyanov, and reply of TH McGlashan, WT Carpenter Jr, July, 861–862
Viral encephalopathy mimicking functional psychosis, LG Wilson, Feb, 165–170
Viral encephalopathy and psychosis (ltr to ed), RM Stewart, RJ Baldessarini, June, 717

PSYCHOSURGERY

Psychiatric test assessment of patients with psychomotor epilepsy, EA Serafetinides, DG Cherlow, July, 844–847
Psychosurgery for political purposes (ltr to ed), PR Breggin, July, 864
Psychosurgery: some current observations, SA Shevitz, March, 266–270

PSYCHOTHERAPY

Another approach to avoidance (ltr to ed), M Blumenfield, and reply of MK Goin, July, 851
Assault on the therapist, RM Whitman, BB Armao, OB Dent, April, 426–429
Attitudes of psychiatric residents toward payment of psychotherapy fees, BS Meyers, Dec, 1460–1462
The behavior therapies: therapeutic breakthrough or latest fad? AK Shapiro, Feb, 154–159
Correlates of patient attendance in an inner-city mental health clinic, TJ Craig, CL Huffine, Jan, 61–65
Countertransference: a neglected subject in clinical supervision, MK Goin, F Kline, Jan, 41-44
The current status of behavioral psychotherapy: theory and practice, IM Marks, March, 253–261
Current trends in the teaching of family therapists, EW Beal, Feb, 137–141
A description and evaluation of an outpatient intensive psychotherapy center, W Swenson, HR Martin, Sept, 1043–1046
Drug and psychotherapy interactions in depression, L. Covi, RS Lipman, RD Alarcon, VK Smith, May, 502–508
Effects of peer review on outpatient psychotherapy: therapist and patient follow-up survey, LL Luft, LM Sampson, D Newman, Aug, 891–895
Follow-up of depressed women after maintenance treatment, MM Weissman, SV Kasl, GL Klerman, July, 757–760
Free psychotherapy: an inquiry into resistance, JL Nash, JQ Cavenar, Sept, 1066–1069
Inspiration of psychotherapists by patients, E Messner, Dec, 1462–1463
Is countertransference an appropriate issue in clinical supervision? (ltr to ed), UP Bhatt, and reply of MK Goin, June, 714–715
Management of interpersonal issues in systematic desensitization, DL Braff, M Raskin, D Geisinger, July, 791–794
"Misleading" concepts in family therapy (ltr to ed), FM Sander, and

reply of LR Robinson, March, 344–345
Overview: research on the psychology of women. II. Women in families, work, and psychotherapy, AM Seiden, Oct, 1111–1123
Patient responsibility and free psychotherapy (ltr to ed), J Paris, Dec, 1471–1472
Patients' expectations of therapeutic improvement and their outcome, S Bloch, G Bond, B Qualls, I Yalom, E Zimmerman, Dec, 1457–1460
Patients' perceptions of the therapeutic relationship and group therapy outcome, AS Gurman, JP Gustafson, Nov, 1290–1294
Principles of the new sex therapy, WH Masters, VE Johnson, May, 548–554
Prognostic correlates of psychotherapy in psychiatric outpatients, AK Shapiro, E Struening, E Shapiro, H Barten, July, 802–808
The psychological treatment of personality disorder, PC Horton, March, 262–265
The psychotherapist and informed consent, JO Noll, Dec, 1451–1453
Psychotherapy fees and residency training, SA Pasternack, P Treiger, Sept, 1064–1066
Rational treatment for an irrational disorder: what does the schizophrenic patient need? PRA May, Sept, 1008–1012
REM sleep and adaptation of psychiatric patients: an application of sleep studies, R Greenberg, CA Pearlman, Oct, 1147–1150
Sex bias in psychotherapy: a failure to confirm, SI Abramowitz, HB Roback, JM Schwartz, A Yasuna, CV Abramowitz, B Gomes, June, 706–709
Should intensive psychotherapy be insured? (ltrs to ed), TW Bittker; WL Allan, and reply of SS Sharfstein, HL Magnas, June, 715–717
Some problems in learning to do "good psychotherapy," M Lakovics, July, 834–837
Strategies and risks in psychotherapy with bilingual patients: the phenomenon of language independence, LR Marcos, M Alpert, Nov, 1275–1278
Therapy groups for women, CS Wolman, March, 274–278
Treatment of requests for sex-change surgery with psychotherapy, M Kirkpatrick, CTH Friedmann, Oct, 1194–1196
Who gets supervised? An extension of patient selection inequity, RW Burgoyne, S Santini, F Kline, FB Staples, Nov, 1313–1315

RAPE

Coping behavior of the rape victim, AW Burgess, LL Holmstrom, April, 413–418
Development of a medical center rape crisis intervention program, SL McCombie, E Bassuk, R Savitz, S Pell, April, 418–421
It is always the woman who is raped, D Metzger, April, 405–408
Rape: "the ultimate violation of the self" (editorial), E Hilberman, April, 436–437
The rape victim: psychodynamic considerations, MT Notman, CC Nadelson, April, 408–413
The "ultimate overstatement"? (ltr to ed), RL Goldstein, and reply of E Hilberman, Sept, 1096

RECORDS

The effects of the sealed record in adoption, AD Sorosky, A Baran, R Pannor, Aug, 900–904
Patient privacy and confidentiality at mental health centers, JO Noll, MJ Hanlon, Nov, 1286–1289
Treatment plans for mental health care, DJ Knesper, D Miller, Jan, 45–50
Two problem-oriented letters (ltrs to ed), PK John; RL Grant, Oct, 1209–1210
The use of problem-oriented medical records in community mental health centers, GM Vickar, M Herjanic, March, 340–341
Use of the problem-oriented medical record in psychiatry: a survey of university based residency training programs, EH Liston, June, 700–703

RESEARCH DESIGN, STATISTICS

The behavior therapies: therapeutic breakthrough or latest fad? AK Shapiro, Feb, 154–159
Breaking into the prison: conducting a medical research project, JS Rubin, Feb, 230–232
Current diagnostic concepts in schizophrenia, WT Carpenter Jr, Feb, 172–177
A methodological question (ltr to ed), AJ Gelenberg, R Mandel, and reply of S Idzorek, July, 860–861
The psychedelic model of schizophrenia: the case of *N,N*-dimethyltryptamine, JC Gillin, J Kaplan, R Stillman, RJ Wyatt, Feb, 203–208
A question of significance (ltr to ed), M Feinberg, and reply of T McGlashan, WT Carpenter Jr, Sept, 1095–1096
A reconsideration of the Kety and associates study of genetic factors in the transmission of schizophrenia, LS Benjamin, 1129–1133
A reply to a rebuttal, LS Benjamin, Dec, 1466
Studies designed to disentangle genetic and environmental variables in schizophrenia: some epistemological questions and answers, SS Kety, Oct, 1134–1137

SCHIZOPHRENIA

Diagnosis

Current diagnostic concepts in schizophrenia, WT Carpenter Jr, Feb, 172–177
Problems in the differential diagnosis of narcolepsy versus schizophrenia, B Shapiro, H Spitz, Nov, 1321–1323

Research

Albinism and schizophreniform psychosis: a pedigree study, M Baron, Sept, 1070–1073
Decreased blood platelet MAO activity in unmedicated chronic schizophrenic patients, EF Domino, SS Khanna, March, 323–326; correction, June, 720
Depression and the reintegration phase of acute schizophrenia, PT Donlon, RT Rada, KK Arora, Nov, 1265–1268
Do dreams have meaning? an empirical inquiry, M Kramer, R Hlasny, G Jacobs, T Roth, July, 778–781
The dopamine hypothesis of schizophrenia: focus on the dopamine receptor, SH Snyder, Feb, 197–202
Estimating the genetic contribution to schizophrenia, SW Matthysse, KK Kidd, Feb, 185–191
The family and schizophrenia, D Reiss, Feb, 181-185
Immunoglobulin levels in psychiatric patients, M Strahilevitz, JB Fleischman, GW Fischer, N Narasimhachari, July, 772–777
The interaction of social class and other factors in the etiology of schizophrenia, ML Kohn, Feb, 177–180
Introduction: current concepts of schizophrenia, RJ Wyatt, Feb, 171–172
An investigation of the postpsychotic depressive syndrome, TH McGlashan, WT Carpenter Jr, Jan, 14–19
Platelet monoamine oxidase activity in schizophrenia, HL White, MN McLeod, JRT Davidson, Oct, 1191–1193
The psychedelic model of schizophrenia: the case of *N,N*-dimethyltryptamine, CJ Gillin, J Kaplan, R Stillman, RJ Wyatt, Feb, 203–208
Psychosis, thought disorder, and regression, NC Andreasen, PS Powers, May, 522–526
Recent developments in the drug treatment of schizophrenia, JM Davis, Feb, 208–214
A reconsideration of the Kety and associates study of genetic factors in the transmission of schizophrenia, LS Benjamin, Oct, 1129–1133
Reduced platelet monoamine oxidase activity in a subgroup of schizophrenia patients, JJ Schildkraut, JM Herzog, PJ Orsulak, SE Edelman, HM Shein, SH Frazier, April, 438–440

A reply to a rebuttal, LS Benjamin, Dec, 1466
Serum creatine phosphokinase in schizophrenia, HY Meltzer, Feb, 192–197
Studies designed to disentangle genetic and environmental variables in schizophrenia: some epistemological questions and answers, SS Kety, Oct, 1134–1137

Treatment

Catatonia, gastric hyperacidity, and fatal aspiration: a preventable syndrome, RF Bort, April, 446–447
ECT as maintenance therapy in schizophrenia (ltr to ed), G Asnis, AN Gabriel, July, 858–859
Effect of drug ritual changes on schizophrenic patients, RW Burgoyne, March, 284–289
A fair comparison? (ltr to ed), HL Freeman, and reply of JS Bockoven, HC Solomon, July, 856–857
Fatal aspiration (ltr to ed), K Solomon, and reply of RF Bort, Nov, 1349–1350
A favorable response to lithium carbonate in a "schizo-affective" father and son, DE Reiser, AB Willett, July, 824–827
Homeopathic dosage in maintenance therapy (ltr to ed), G Middlekauff, and reply of JM Davis, July, 857
Lithium in schizophrenia (ltr to ed), A Taheri, Oct, 1208
Maintenance antipsychotic therapy: is the cure worse than the disease? G Gardos, JO Cole, Jan, 32–36
Maintenance therapy guidelines (ltr to ed), K Solomon, and reply of JM Davis, July, 857–858
Penfluridol in the treatment of newly admitted schizophrenic patients in a brief therapy unit, G Chouinard, L Annable, July, 820–823
Postpsychotic state, convalescent environment, and therapeutic relationship in schizophrenic outcome, L Kayton, J Beck, SD Koh, Nov, 1269–1274
A query on follow-up results (ltr to ed), RB Davis, and reply of JS Bockoven, Sept, 1089
Rational treatment for an irrational disorder: what does the schizophrenic patient need? PRA May, Sept, 1008–1012
Recent developments in the drug treatment of schizophrenia, JM Davis, Feb, 208–214
Short versus long hospitalization: a prospective controlled study. IV. One-year follow-up results for schizophrenic patients, ID Glick, WA Hargreaves, J Drues, JA Showstack, May, 509–514
Some observations on maintenance therapy (ltr to ed), G Singleton, Sept, 1092–1093

SEXUALITY

The behavior of hypersexual delinquent girls, JD Goodman, June, 663–668
The cessation of marital intercourse, JN Edwards, A Booth, Nov, 1333–1336
Characteristics of "erotic" practitioners, SH Kardener, M Fuller, IN Mensh, Nov, 1324–1325
Confirming a side effect (ltr to ed), MA Amdur, July, 864–865
Early sex education in relationship to later coital and reproductive behavior: evidence from Jamaican women, EB Brody, F Ottey, J LaGranade, Aug, 969–972
Forensic psychiatry: profiles of two types of sex offenders, FA Henn, M. Herjanic, RH Vanderpearl, June, 694–696
The legal implications of sexual activity between psychiatrist and patient, AA Stone, Oct, 1138–1141
Male transsexuals in the homosexual subculture, EM Levine, Nov, 1318–1321
Overview: research on the psychology of women. I. Gender differences and sexual and reproductive life, AM Seiden, Sept, 995–1007
Physicians' erotic and nonerotic physical involvement with patients, JA Perry, July, 838–840
Principles of the new sex therapy, WH Masters, VE Johnson, May, 548–554
Pseudohomosexuality in feminist students, Z DeFries, April, 400–404
Sex therapy and psychophysiological research, RC Schiavi, May, 562–566
Sexual attitudes of hospital personnel: a model for continuing education, DJ Withersty, May, 573–575
Thioridazine and sexual dysfunction, J Kotin, DE Wilbert, D Verburg, SM Soldinger, Jan, 82–85
Treatment for the parents of feminine boys, LE Newman, June, 683–687
Treatment of requests for sex-change surgery with psychotherapy, M Kirkpatrick, CTH Friedmann, Oct, 1194–1196
Virilizing influences, sexual behavior, and IQ (ltr to ed), V Abernethy, and reply of JD Goodman, Nov, 1350–1351

SEX THERAPY AND SEX EDUCATION

Behavior therapy and sex therapy, JP Brady, Aug, 896–899
Early sex education in relationship to later coital and reproductive behavior: evidence from Jamaican women, EB Brody, F Ottey, J LaGranade, Aug, 969–972
Principles of the new sex therapy, WH Masters, VE Johnson, May, 548–554
Profiles of couples seeking sex therapy and marital therapy, E Frank, C Anderson, DJ Kupfer, May, 559–562
The role of sex therapy in marital therapy, CJ Sager, May 555–559
Sex therapy and psychophysiological research, RC Schiavi, May, 562–566
Sexual attitudes of hospital personnel: a model for continuing education, DJ Withersty, May, 573–575
Training and accreditation for the treatment of sexual disorders, JK Meyer, April, 389–394

SLEEP AND SLEEP DISORDERS

The concept of drug automatism, MI Good, Aug, 948–952
EEG sleep changes as predictors in depression, DJ Kupfer, FG Foster, L Reich, KS Thompson, B Weiss, June, 622–626
Pavor nocturnus: a complication of single daily tricyclic or neuroleptic dosage, A Flemenbaum, May, 570–572
Problems in the differential diagnosis of narcolepsy versus schizophrenia, B Shapiro, H Spitz, Nov, 1321–1323
REM sleep and adaptation of psychiatric patients: an application of sleep studies, R Greenberg, CA Pearlman, Oct, 1147-1150
Self-reports versus sleep laboratory findings in 122 drug-free subjects with complaints of chronic insomnia, MA Carskadon, WC Dement, MM Mitler, C Guilleminault, VP Zarcone, R Spiegel, Dec, 1369–1376
Somnambulism and bedtime medication (ltr to ed), L Huapaya, Oct, 1207

SOCIAL CLASS

The interaction of social class and other factors in the etiology of schizophrenia, ML Kohn, Feb, 177–180

SOCIOPATHY

Assessment of sociolegal judgment of offenders, MS Cerino, AJ Dy, Aug, 973–975
Was "sociopathy" ever a diagnosis? (ltr to ed), RL Jenkins, and reply of DO Lewis, April, 456–457

STUDENTS

The frequency of suicide attempts: a retrospective approach applied to college students, BL Mishara, AH Baker, TT Mishara, July, 841–844
Pseudohomosexuality in feminist students, Z DeFries, April, 400–404
Student mental health services and departments of psychiatry, CB Reifler, R Babineau, Aug, 967–968

SUICIDE

Carbon monoxide encephalopathy: need for appropriate treatment, R Ginsburg, J Romano, March, 317–320
Cluster analysis profiles of suicide attempters, A Kiev, Feb, 150–153
The frequency of suicide attempts: a retrospective approach applied to college students, BL Mishara, AH Baker, TT Mishara, July, 841–844
Psychiatric illness in homicide victims, M Herjanic, DA Meyer, June, 691–693

SUPERVISION

Countertransference: a neglected subject in clinical supervision, MK Goin, F Kline, Jan, 41–44
Is countertransference an appropriate issue in clinical supervision? (ltr to ed), UP Bhatt, and reply of MK Goin, June, 714–715
Who gets supervised? An extension of patient selection inequity, RW Burgoyne, S Santini, F Kline, FB Staples, Nov, 1313–1315

SYSTEMS THEORY

Alcohol and drug abuse consultation in the general hospital: a systems approach, M Galanter, TB Karasu, JF Wilder, Aug, 930–934
A general systems approach to severe family pathology, S Fleck, June, 669–673

TELEVISION

Focusing on television (ltr to ed), MP Dumont, April, 457
A television stereotype (ltr to ed), DA Dansak, April, 457
The use of two-way TV in bringing mental health services to the inner city, N Straker, P Mostyn, C Marshall, Oct, 1202–1205

TESTS, PSYCHOLOGICAL

The broad role of ego functions assessment, L Bellak, M Sheehy, Nov, 1259–1264
Digit-symbol performance in methadone-treated ex-heroin addicts, PW Appel, NB Gordon, Nov, 1337–1339
Psychiatric test assessment of patients with psychomotor epilepsy, EA Serafetinides, DG Cherlow, July, 844–847

TOXIC STATES

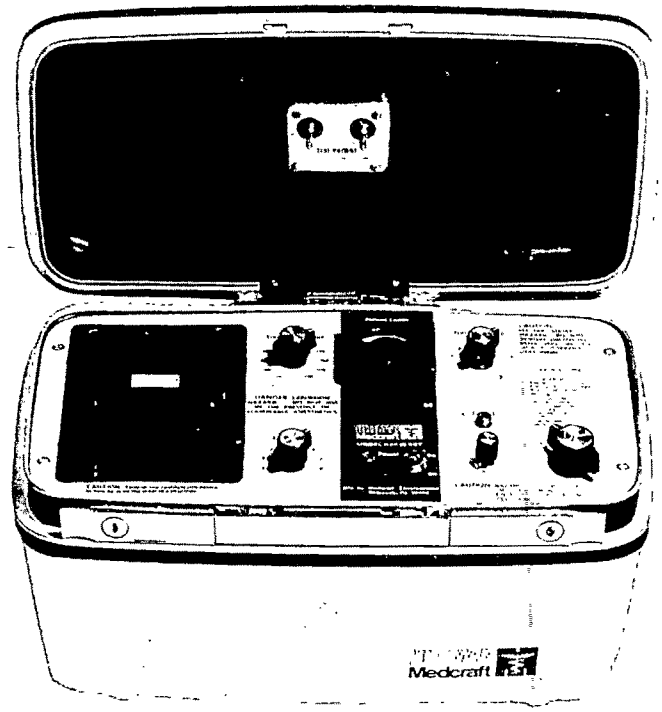
Carbon monoxide encephalopathy: need for appropriate treatment, R Ginsburg, J Romano, March, 317–320
Diagnosis and treatment after CO poisoning (ltr to ed), RA Remick, Aug, 978
The 'intoxication state of consciousness'': a model for alcohol and drug abuse, M Galanter, June, 635–640
Lead and hyperactivity: behavioral response to chelation: a pilot study, OJ Davis, SP Hoffman, J Sverd, J Clark, K Voeller, Oct, 1155–1158
Mania and bromism: a case report and a look to the future, AJ Sayed, Feb, 228–229
Questioning a diagnosis (ltrs to ed), JW Jefferson; M Abbas, and reply to AJ Sayed, Oct, 1208–1209
Reversal of tricyclic-overdosage-induced central anticholinergic syndrome by physostigmine, PC Holinger, HL Klawans, Sept, 1018–1023
Subtle neuropsychiatric sequelae of carbon monoxide intoxication: two case reports, JW Jefferson, Aug, 961–964
Tracking difficulties and paranoid ideation during hashish and alcohol intoxication, FT Melges, Sept, 1024–1028
Treatment of tricyclic intoxication, RA Munoz, Sept, 1085–1087

TRANSCULTURAL PSYCHIATRY

The family in exile: Cuban expatriates in the United States, RD Rumbaut, RG Rumbaut, April, 395–399
In search of the true amok: amok as viewed within the Malay culture, JE Carr, EK Tan, Nov, 1295–1299
Psychiatry and folk healing: a dichotomy? P Ruiz, J Langrod, Jan, 95–97

TRANSSEXUALISM

Male transsexuals in the homosexual subculture, EM Levine, Nov, 1318–1321
Transsexualism in two male triplets, EA McKee, HB Roback, MH Hollender, March, 334–337
Treatment of requests for sex-change surgery with psychotherapy, M Kirkpatrick, CTH Friedmann, Oct, 1194–1196



VIOLENCE

Adolescent parricide: a comparison with other adolescent murder, BF Corder, BC Ball, TM Haizlip, R Rollins, R Beaumont, Aug, 957–961
Assault on the therapist, RM Whitman, BB Armao, DB Dent, April, 426–429
Assaults on psychiatrists by patients, DJ Madden, JR Lion, MW Penna, April, 422–425
Capgras syndrome: a case involving violence (ltr to ed), R Weinstock, July, 855
The effect of lithium on impulsive aggressive behavior in man, MH Sheard, JL Marini, CI Bridges, E Wagner, Dec, 1409–1413
Examining the pavement (ltr to ed), SL Auster, and reply of A Zitrin, AS Hardesty, EI Burdock, AK Drossman, July, 863–864
Forensic psychiatry: profiles of two types of sex offenders, FA Henn, M Herjanic, RH Vanderpearl, June, 694–695
More violent Capgras (ltr to ed), DL Crane, Nov, 1350
The murdered child and his killers, D Kaplun, R Reich, July, 809–813
Nursing aides and patient violence, P Levy, P Hartocollis, April, 429–431
Psychiatric illness in homicide victims, M Herjanic, DA Meyer, June, 691–693
In search of the true amok: amok as viewed within the Malay culture, JE Carr, EK Tan, Nov, 1295–1299
A television stereotype (ltr to ed), DA Dansak, April, 457
A violence clinic: three years' experience, JR Lion, DJ Madden, RL Christopher, April, 432–435
The why of fragging, TC Bond, Nov, 1328–1331

WOMEN

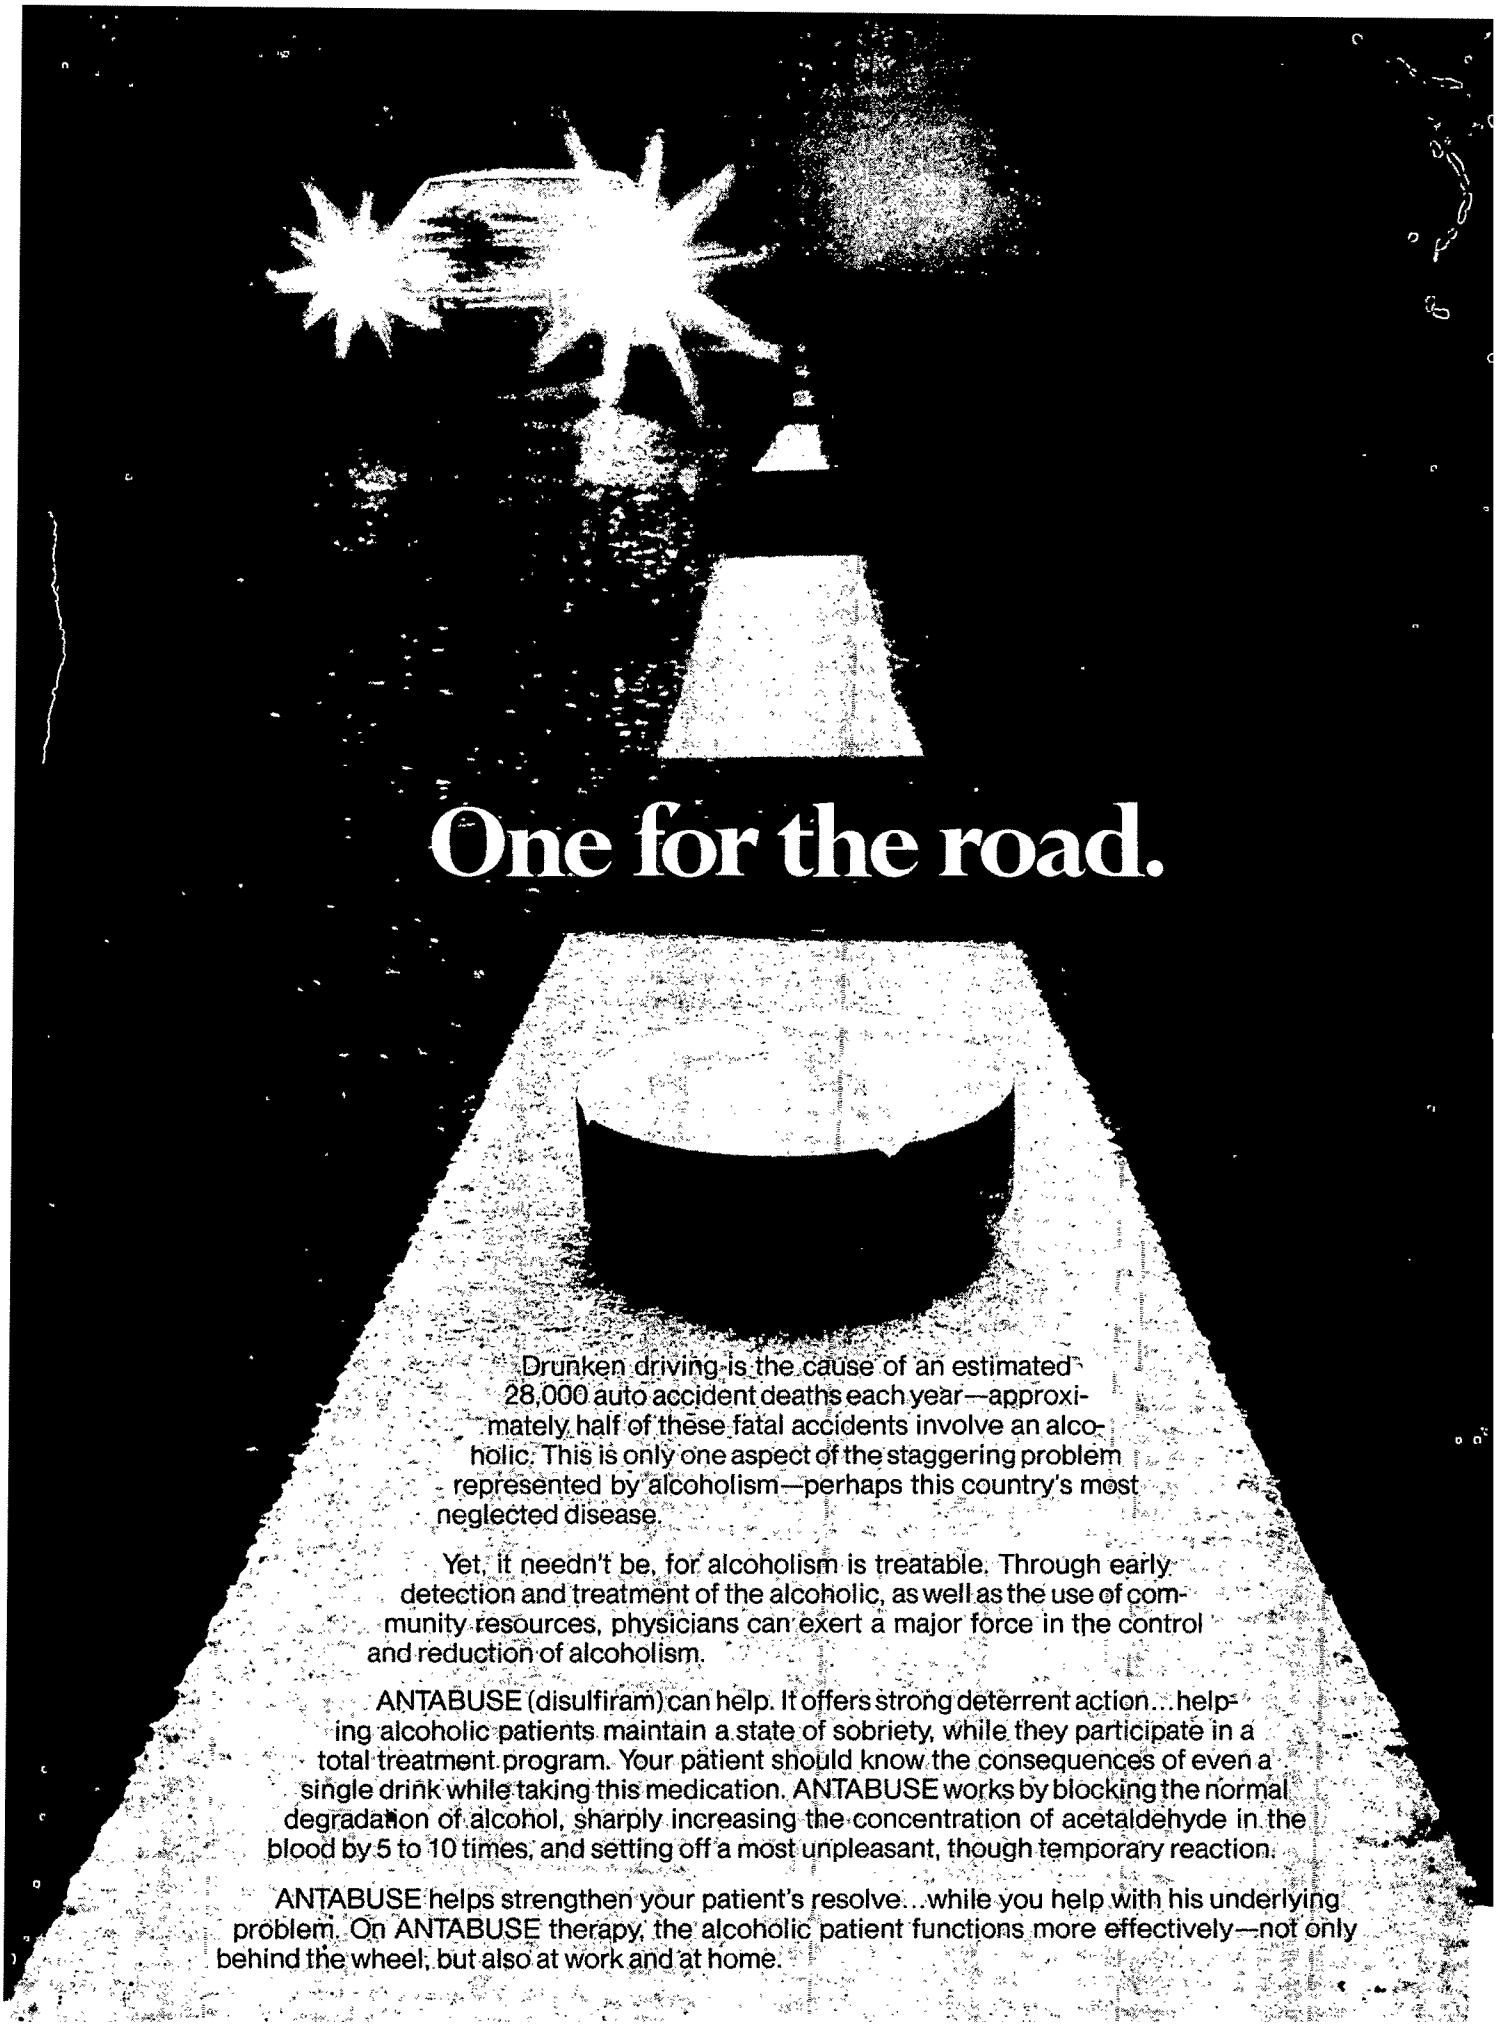
Coping behavior of the rape victim, AW Burgess, LL Holmstrom, April, 413–418
Cultural perspectives on the impact of women's changing roles on psychiatry, V Abernethy, June, 657–661
Development of a medical center rape crisis intervention program, SL McCombie, E Bassuk, R Savitz, S Pell, April, 418–421
Early sex education in relationship to later coital and reproductive behavior: evidence from Jamaican women, EB Brody, F Ottey, J LaGranade, Aug, 969–972
Editorial practices of psychiatric and related journals: implications for women, EP Benedek, Jan, 89–92
Follow-up of depressed women after maintenance treatment, MM Weissman, SV Kasl, GL Klerman, July, 757–760
Impact of a district branch task force on women, E Hilberman, M Gispert, J Harper, Oct, 1159–1164
It is always the woman who is raped, D Metzger, April, 405–408
Nursing aides and patient violence, P Levy, P Hartocollis, April, 429–431
Overview: research on the psychology of women. I. Gender differences and sexual and reproductive life, AM Seiden, Sept, 995–1007
Overview: research on the psychology of women. II. Women in families, work, and psychotherapy, AM Seiden, Oct, 1111–1123
Physicians' erotic and nonerotic physical involvement with patients, JA Perry, July, 838–840
Pseudohomosexuality in feminist students, Z DeFries, April, 400–404
Psychiatrist-wife-mother: some aspects of role integration, M Scher, E Benedek, A Candy, K Carey, J Mules, B Sachs, July, 830–834
Rape: "the ultimate violation of the self" (editorial), E Hilberman, April, 436–437
The rape victim: psychodynamic considerations, MT Notman, CC Nadelson, April, 408–413
Sex bias in psychotherapy: a failure to confirm, SI Abramowitz, HB Roback, JM Schwartz, A Yasuna, CV Abramowitz, B Gomes, June, 706–709
On sexism in the language (ltr to ed), K Solomon, Dec, 0000–0000
Therapy groups for women, CS Wolman, March, 274–278
The "ultimate overstatement"? (ltr to ed), RL Goldstein, and reply of E Hilberman, Sept, 1096
Women in psychiatry: a review, NA Roeske, April, 365–372

The B24 III

UL LISTED

...a new generation of electroconvulsive therapy instrumentation from Medcraft.

Designed with patient and operator safety in mind, this new series of instrumentation meets the rigorous requirements for listing by Underwriters Laboratories — UL 544, Standards for Medical and Dental Equipment. The B24 III provides the physician with the ultimate in precision dosage levels. Consistancy of desired output level is assured with the following features:



- Line Voltage Compensation — allows compensation for fluctuations in incoming line voltages.
- Pre-programmed Voltage Selection — choice of eleven voltage levels from 70 volts to 170 volts.
- Automatic Treatment Timing — adjustable from 0.1 second to 1.0 second with or without Glissando.
- Current Output Indicators — visual assurance of current flow during treatment.

Exclusive Patient Test Module allows a complete systems integrity check of instrumentation prior to treatment. Clinical accuracy and dependability are assured by the use of 100% solid state circuitry. Double shielded transformer provides an additional margin of treatment safety. For ordering information, specifications and prices, write or call directly to:

One for the road.

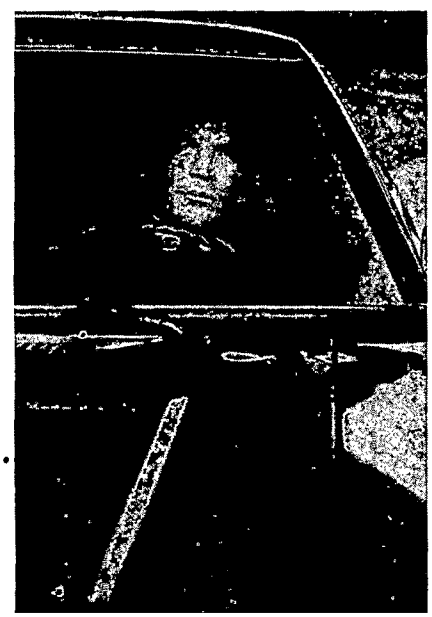
Drunken driving is the cause of an estimated 28,000 auto accident deaths each year—approximately half of these fatal accidents involve an alcoholic. This is only one aspect of the staggering problem represented by alcoholism—perhaps this country's most neglected disease.

Yet, it needn't be, for alcoholism is treatable. Through early detection and treatment of the alcoholic, as well as the use of community resources, physicians can exert a major force in the control and reduction of alcoholism.

ANTABUSE (disulfiram) can help. It offers strong deterrent action...helping alcoholic patients maintain a state of sobriety, while they participate in a total treatment program. Your patient should know the consequences of even a single drink while taking this medication. ANTABUSE works by blocking the normal degradation of alcohol, sharply increasing the concentration of acetaldehyde in the blood by 5 to 10 times, and setting off a most unpleasant, though temporary reaction.

ANTABUSE helps strengthen your patient's resolve...while you help with his underlying problem. On ANTABUSE therapy, the alcoholic patient functions more effectively—not only behind the wheel, but also at work and at home.

BRIEF SUMMARY
(For full prescribing information, see package circular.)
ANTABUSE® (disulfiram) In Alcoholism
INDICATION: ANTABUSE is an aid in the management of selected chronic alcoholic patients who want to remain in a state of enforced sobriety so that supportive and psychotherapeutic treatment may be applied to best advantage. (Used alone, without proper motivation and without supportive therapy, ANTABUSE is not a cure for alcoholism, and it is unlikely that it will have more than a brief effect on the drinking pattern of the chronic alcoholic.)
CONTRAINDICATIONS: Patients who are receiving or have recently received metronidazole, paraldehyde, alcohol, or alcohol-containing preparations, e.g. cough syrups, tonics, and the like, should not be given ANTABUSE.
ANTABUSE is contraindicated in the presence of severe myocardial disease or coronary occlusion, psychoses, or hypersensitivity



WARNINGS: ANTABUSE should never be administered to a patient when he is in a state of alcohol intoxication or without his full knowledge.
The physician should instruct relatives accordingly.

The patient must be fully informed of the ANTABUSE-alcohol reaction. He must be strongly cautioned against surreptitious drinking while taking the drug, and he must be fully aware of possible consequences. He should be warned to avoid alcohol in disguised form, *i.e.* in sauces, vinegars, cough mixtures, and even aftershave lotions and back rubs. He should also be warned that reactions may occur with alcohol up to 14 days after ingesting ANTABUSE.
THE ANTABUSE-ALCOHOL REACTION:
ANTABUSE plus alcohol, even small amounts, produces flushing, throbbing in head and neck, throbbing headache, respiratory difficulty, nausea, copious vomiting, sweating, thirst, chest pain, palpitation, dyspnea, hyperventilation, tachycardia, hypotension, syncope, marked uneasiness, weakness, vertigo, blurred vision, and confusion. In severe reactions there may be respiratory depression, cardiovascular collapse, arrhythmias, myocardial infarction, acute congestive heart failure, unconsciousness, convulsions, and death.
The intensity of the reaction varies with each individual, but is generally proportional to the amounts of ANTABUSE (disulfiram) and alcohol ingested. Mild reactions may occur in the sensitive individual when the blood alcohol concentration is increased to as little as 5 to 10 mg. per 100 cc. Symptoms are fully developed at 50 mg. per 100 cc., and unconsciousness usually results when the blood alcohol level reaches 125 to 150 mg.
The duration of the reaction varies from 30 to 60 minutes to several hours in the more severe cases, or as long as there is alcohol in the blood.
DRUG INTERACTIONS: Disulfiram appears to decrease the rate at which certain drugs are metabolized and so may increase the blood levels and the possibility of clinical toxicity of drugs given concomitantly.
Disulfiram should be used with caution in those patients receiving diphenylhydantoin and its congeners, since toxic levels of these antiepileptic agents have been reported during concomitant disulfiram therapy.
It may be necessary to adjust the dosage of oral anticoagulants upon beginning or stopping disulfiram, since disulfiram may prolong prothrombin time.
Patients taking isoniazid when disulfiram is given should be observed for the appearance of unsteady gait or marked changes in mental status and the disulfiram discontinued if such signs appear.
CONCOMITANT CONDITIONS: Because of the possibility of an accidental ANTABUSE-alcohol reaction, ANTABUSE (disulfiram) should be used with extreme caution in patients with any of the following conditions: diabetes mellitus, hypothyroidism, epilepsy, cerebral damage, chronic and acute nephritis, hepatic cirrhosis or insufficiency.
USAGE IN PREGNANCY: The safe use of this drug in pregnancy has not been established. Therefore, ANTABUSE should be used during pregnancy only when, in the judgment of the physician, the probable benefits outweigh the possible risks.
PRECAUTIONS: It is suggested that every patient under treatment carry an Identification Card, stating that he is receiving ANTABUSE and describing the symptoms most likely to occur as a result of the ANTABUSE-alcohol reaction. In addition, this card should indicate the physician or institution to be contacted in emergency. (Cards may be obtained from Ayerst Laboratories upon request.)
Alcoholism may accompany or be followed by dependence on narcotics or sedatives. Barbiturates have been administered concurrently with ANTABUSE (disulfiram) without untoward effects, but the possibility of initiating a new abuse should be considered.
Base line and follow-up transaminase tests (10-14 days) are suggested to detect any hepatic dysfunction that may result with ANTABUSE therapy. In addition, a complete blood count and a sequential multiple analysis-12 (SMA-12) test should be made every six months.
ADVERSE REACTIONS: (See Contraindications, Warnings, and Precautions.)
Optic neuritis, peripheral neuritis, and polyneuritis may occur following administration of ANTABUSE.
Occasional skin eruptions are, as a rule, readily controlled by concomitant administration of an antihistaminic drug.
In a small number of patients, a transient mild drowsiness, fatigability, impotence, headache, acneform eruptions, allergic dermatitis, or a metallic or garlic-like aftertaste may be experienced during the first two weeks of therapy. These complaints usually disappear spontaneously with the continuation of therapy or with reduced dosage.
Psychotic reactions have been noted, attributable in most cases to high dosage, combined toxicity (with metronidazole or isoniazid), or to the unmasking of underlying psychoses in patients stressed by the withdrawal of alcohol.
One case of cholestatic hepatitis has been reported, but its relationship to ANTABUSE has not been unequivocally established.
DOSAGE AND ADMINISTRATION: ANTABUSE (disulfiram) should never be administered until the patient has abstained from alcohol for at least 12 hours.
INITIAL DOSAGE SCHEDULE: In the first phase of treatment, a maximum of 500 mg. daily is given in a single dose for one to two weeks. Although usually taken in the morning, ANTABUSE may be taken on retiring by patients who experience a sedative effect. Alternatively, to minimize, or eliminate, the sedative effect, dosage may be adjusted downward.
MAINTENANCE REGIMEN: The average maintenance dose is 250 mg. daily (range, 125 to 500 mg.); it should not exceed 500 mg. daily.
NOTE: Occasional patients, while seemingly on adequate maintenance doses of ANTABUSE, report that they are able to drink alcoholic beverages with impunity and without any symptomatology. All appearances to the contrary, such patients must be presumed to be disposing of their tablets in some manner without actually taking them. Until such patients have been observed reliably taking their daily ANTABUSE tablets (preferably crushed and well mixed with liquid), it cannot be concluded that ANTABUSE is ineffective.
DURATION OF THERAPY: The daily, uninterrupted administration of ANTABUSE must be continued until the patient is fully recovered socially and a basis for permanent self-control is established. Depending on the individual patient, maintenance therapy may be required for months or even years.
TRIAL WITH ALCOHOL: During early experience with ANTABUSE, it was thought advisable for each patient to have at least one supervised alcohol-drug reaction. More recently, the test reaction has been largely abandoned. Furthermore, such a test reaction should never be administered to a patient over 50 years of age. A clear, detailed, and convincing description of the reaction is felt to be sufficient in most cases.
However, where a test reaction is deemed necessary, the suggested procedure is as follows:
After the first one to two weeks' therapy with 500 mg. daily, a drink of 15 cc. (1/2 oz.) of 100 proof whiskey or equivalent is taken slowly. This test dose of alcoholic beverage may be repeated once only so that the total dose does not exceed 30 cc. (1 oz.) of whiskey. Once a reaction develops, no more alcohol should be consumed. Such tests should be carried out only when the patient is hospitalized, or comparable supervision and facilities, including oxygen, are available.
MANAGEMENT OF ANTABUSE (DISULFIRAM)-ALCOHOL REACTION: In severe reactions, whether caused by an excessive test dose or by the patient's unsupervised ingestion of alcohol, supportive measures to restore blood pressure and treat shock should be instituted. Other recommendations include: oxygen, carbogen (95 per cent oxygen and 5 per cent carbon dioxide), vitamin C intravenously in massive doses (1 Gm.), and ephedrine sulfate. Antihistamines have also been used intravenously. Potassium levels should be monitored particularly in patients on digitalis since hypokalemia has been reported.
HOW SUPPLIED: No. 809—Each tablet (scored) contains 250 mg. disulfiram, in bottles of 100.
No. 810—Each tablet (scored) contains 500 mg. disulfiram, in bottles of 50 and 1,000. **7626**

The Rape Victim

by Elaine Hilberman, M.D.

Mythologies about rape are legion. However, in recent years behavioral scientists have accumulated a body of information about rape and about an unfolding series of reactions experienced by the victim after rape. The aim of this concise, tightly reasoned book is to summarize what is now known about the needs and experiences of the victim and her family, and to provide a framework in which the clinician can more knowledgeably supply assistance and support. This document, published by the American Psychiatric Association, is the result of a project of the Association's Committee on Women.

Pointing out that the profound impact of rape stress is best understood in the context of rape as "a crime against the person and not the hymen," Dr. Hilberman sees rape as the ultimate violation of the self short of homicide, as an act of violence and humiliation in which not only is the victim's very existence threatened, and her inner and most private space invaded, but her autonomy and control are totally demolished. Dr. Hilberman shows that if and when the victim reports the crime, she is confronted with a complex series of yet additional stresses growing out of her contact with the hospital, police, courts, media and community opinion. Additionally, her crisis differs from other crises in that her usual social support system is likely to be disrupted. Her immediate needs are for empathy and safety, and a sense of control over what is happening in her dealings with the several agencies. Dr. Hilberman shows that in the absence of sensitivity to these needs, the experience of reporting becomes another assault.

This book presents a professional, sobering, and balanced picture of the problems of the rape victim and details what the clinician must know—about local hospital policy, criminal justice procedure, rape statutes, and community attitudes and services—in order to be able to treat victims with an understanding of the larger context in which rape occurs.

ELAINE HILBERMAN, M.D., *is in the Department of Psychiatry at the University of North Carolina School of Medicine.*

Out of touch

but not beyond reach...

Help restore reality

- low dose, high potency phenothiazine useful for inpatient and outpatient treatment
- helps orient psychiatric patients to their surroundings
- effective with minimal sedation, usually produces little lethargy or drowsiness

Trilafon®
brand of
perphenazine, NF
for management of disturbed behavior in schizophrenic and manic states

Versatile Dosage	
Injection	5 mg/ml, 1 ml ampul
Concentrate	16 mg/5 ml, 120 ml bottle
Tablets	2,4,8,16 mg
REPETABS® Tablets 8 mg brand of repeat-action tablets	

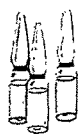
Please see next page for prescribing information.

Trilafon®

brand of perphenazine, NF

For management of schizophrenic and manic disorders in psychiatric hospitals, mental health clinics, and with outpatient treatment

TABLETS
for maintenance or control of patients in hospital or home



BENEFITS

- generally improve cooperation and communication
- decrease need for custodial care, hasten discharge

CONCENTRATE
for maintenance or control of uncooperative in-hospital patients

- easily mixes with most liquids
- ensures easy, steady, certain administration

INJECTION
for emergency control of uncooperative in-hospital patients

- usually takes effect in 10 minutes
- average duration of effect is 6 hours

TRILAFON® Tablets

brand of perphenazine, NF

REPETABS® Tablets
Concentrate
Injection

CONTRAINDICATIONS TRILAFON is contraindicated in drug-associated central nervous system depression (barbiturates, alcohol, narcotics, analgesics, antihistamines). Perphenazine is contraindicated in the presence of existing blood dyscrasias, bone marrow depression and pre-existing liver damage, and in patients who are hypersensitive to perphenazine.

TRILAFON **Injection** should not be given to patients in coma or severely depressed states.

WARNINGS **Dosage in pregnancy:** Perphenazine should only be given to pregnant patients when, in the judgment of the physician, the potential benefits outweigh the possible risks.

Perphenazine can lower the convulsive threshold in susceptible individuals; it should be used with caution in patients with convulsive disorders. If the patient is being treated with an anticonvulsant agent, increased dosage of that agent may be required when perphenazine is used concomitantly.

Perphenazine should be used with caution in patients with psychic depression.

Perphenazine is not recommended for children under 12 years of age.

Perphenazine may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery.

PRECAUTIONS As with any potent medication, patients receiving perphenazine should be under medical supervision, particularly if they are receiving high doses. Patients who have had any severe reaction to phenothiazines or to imipramine should be treated cautiously, under close medical supervision.

Although the following adverse reactions have not been reported in patients treated with perphenazine, the possibility that they might occur with TRILAFON should be considered: blood dyscrasias (pancytopenia, thrombocytopenic purpura, leukopenia, eosinophilia); liver damage (biliary stasis); narrowing of the visual fields; pigmentation of the retina, cornea, or lens; cerebral edema; polyphagia; photophobia; hyperpyrexia.

If hypotension develops, levarterenol (norepinephrine) can be used, but not epinephrine, because epinephrine's action is blocked and partly reversed by perphenazine. Severe, acute hypotension has occurred with the use of phenothiazines and is of particular concern in patients with mitral insufficiency or pheochromocytoma.

A significant rise in body temperature may indicate an idiosyncratic reaction to perphenazine; treatment with perphenazine should be stopped if this occurs.

The antiemetic effect of perphenazine can obscure signs of toxicity due to overdosage of other drugs, or mask the symptoms of disease (eg, brain tumor or intestinal obstruction).

Contact dermatitis has been reported with a perphenazine solution; therefore, contact of hands or clothing by those handling perphenazine solutions should be avoided.

POTENTIATION Since phenothiazines can potentiate the central-nervous-system-depressant actions of opiates, antihistamines, barbiturates, and alcohol, less than the usual dosage of these agents is required when they are administered concomitantly with TRILAFON. Patients should be cautioned that their response to alcohol may be increased while they are being treated with TRILAFON.

Phenothiazines also potentiate the effects of atropine, heat, and phosphorus insecticides, and should be used with caution in persons exposed to these agents.

ADVERSE REACTIONS *Extrapyramidal reactions:* dystonia including protrusion, discoloration, aching and rounding of the tongue; tonic spasm of the masticatory muscles, tight feeling in the throat, slurred speech, dysphagia, oculogyric crisis, trismus, torticollis, retrocollis, muscle weakness, and aching and numbness of the limbs, akathisia; motor restlessness; dyskinesia, parkinsonism; hyperreflexia; and ataxia. The incidence and severity of these reactions usually increase with increased dosage, but have occurred in some patients receiving low dosage. Reduction in dosage or treatment with an antispasmodic agent will usually control extrapyramidal reactions. In some instances, however, these reactions may persist after discontinuation of treatment with perphenazine.

Persistent tardive dyskinesia: As with all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear to be irreversible. The syndrome is characterized by rhythmical involuntary movements of the tongue, face, mouth or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities. There is no known effective treatment for tardive dyskinesia; antiparkinsonism agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been reported that fine, vermicular movements of the tongue may be an early sign of the syndrome, and if the medication is stopped at that time the syndrome may not develop.

Allergic reactions: erythema, pruritus, urticaria, eczema, anaphylactoid reactions, and local and generalized edema. In extremely rare instances, individual idiosyncrasy or hypersensitivity to phenothiazines has resulted in cerebral edema, circulatory collapse, and death. Photosensitization, asthma, and exfoliative dermatitis have also occurred in patients treated with phenothiazines.

Autonomic reactions: blurred vision, dry mouth or salivation, nasal congestion, nausea, vomiting, hypertension, tachycardia, hypotension, anorexia, urinary frequency or incontinence, and constipation. Significant autonomic effects have been infrequent in patients receiving less than 24 mg. perphenazine daily.

Other reactions: endocrine disturbances (lactation, gynecomastia, galactorrhea, disturbances in the menstrual cycle), headaches, mild insomnia, altered cerebrospinal fluid proteins, ECG abnormalities, reactivation of psychosis, paradoxical excitement, paranoid-like reactions, catatonia, and systemic lupus erythematosus-like syndrome. Hypnotic effects appear to be minimal, particularly in patients who are permitted to remain active. The following adverse reactions, though rare, have also been reported to be associated with perphenazine treatment: agranulocytosis; jaundice; hyperpigmentation of the skin; grand mal convulsions; failure of ejaculation; hyperglycemia.

Side effects with intramuscular TRILAFON **Injection** have been infrequent and transient. Dizziness or significant hypotension after treatment with TRILAFON (perphenazine) **Injection** is a rare occurrence.

CASE STUDIES OF THE CLINICAL INTERPRETATION OF THE BENDER GESTALT TEST: Illustrations of the Interpretive Process for Graduate Training and Continuing Professional Education *by* **Clifford M. DeCato** *and* **Robert J. Wicks,** *both of Hahnemann Medical College and Hospital, Philadelphia, Pennsylvania. Foreword by* **Zygmunt A. Piotrowski.** Through the presentation of both child and adult cases, this book establishes the Bender Gestalt Test (BGT) as an effective means of assessing personality dynamics, developmental level and psychopathology. It goes beyond the mere listing of diagnostic indicators to clearly illustrate how clinicians may integrate these findings with those of other investigative sources. Basic instructions for the administration of the BGT are also presented. *'76, 152 pp., 31 il., $9.75*

THE EVOLUTION AND CHEMISTRY OF AGGRESSION *by* **Delbert D. Thiessen,** *Univ. of Texas, Austin. Foreword by* **I. Newton Kugelmass.** Two important facets of aggression — its evolution and the chemical control of its expression — are analyzed in this fascinating book. The author explores the phylogenetic history of aggression and emphasizes its adaptive significance. He outlines several genetic correlates of aggression and suggests how competition shapes the social and reproductive organization of populations. The effects of hormones and sex steroids on aggressive patterns are examined, as are the significance of chemosignals in directing aggression, brain biochemistry, and the ways in which pharmacological substances affect aggression. *'76, 232 pp., 38 il., 27 tables, $18.50*

HYPNOSIS AND BEHAVIOR THERAPY *edited by* **Edward Dengrove.** *(42 Contributors)* Directed toward behavior therapists, hypnotherapists and related specialists, this book will acquaint practitioners of one school with the techniques of the other. Following introductory definitions and descriptions of behavior therapy and hypnosis, a section is devoted to experiments dealing with the effects of hypnosis upon conditionability and other basic phenomena underlying behavior therapy. Following this are discussions of the use of behavior therapy techniques by hypnotherapists and, conversely, the use of hypnosis in behavior therapy. *'76, 428 pp., 30 il., 6 tables, $26.75*

LEGACIES IN THE STUDY OF BEHAVIOR: The Wisdom and Experience of Many *edited by* **Joseph Warren Cullen,** *National Institutes of Health, Bethesda, Maryland. (11 Contributors)* Directed primarily toward young scientists and scholars of behavioral science and biomedical research, this volume was written by eleven internationally renowned scientists whose experience and wisdom have provided, and continue to provide, many avenues of profitable research. They discuss scientific issues which they propose as areas of pressing interest for the scientific community in general and the behavioral community in particular. A sampling of topics would include personality as an integrative concept in psychology, exploring with drugs, medical research in a federal agency and man's nonphysical nature. *'75, 288 pp., 38 il., $17.50*

ACUTE GRIEF AND THE FUNERAL *edited by* **Vanderlyn R. Pine,** *State Univ. of New York, New Paltz;* **Austin H. Kutscher** *and* **David Peretz,** *both of Columbia Univ., New York City;* **Robert C. Slater,** *Univ. of Minnesota, Minneapolis;* **Robert DeBellis,** *Columbia Univ., New York City,* **Robert J. Volk,** *Burlington, Vermont; and* **Daniel J. Cherico,** *Columbia Univ., New York City. (47 Contributors)* The psychological and social impact of bereavement during the period of acute grief is comprehensively covered in this impressive thanatological collection. The various articles examine the roles of psychiatrist, funeral director, educator and minister in counseling the bereaved. A wide range of other topics are also examined. *'76, 328 pp., 1 il., 26 tables, $16.50*

OBESITY: Etiology, Treatment and Management *edited by* **Milton V. Kline,** *The Institute for Research in Hypnosis, New York;* **Lester L. Coleman,** *Albert Einstein College of Medicine, New York; and* **Erika E. Wick,** *St. John's Univ., Jamaica, New York. (39 Contributors)* In addition to full clinical coverage, material is presented which deals with the extent of the problem of obesity, the complications and hazards of obesity, the attempt to classify obesity within a psychodynamic and clinical orientation, and the types of obesity which are encountered in the daily practice of psychotherapy and medicine. Some recent contributions emphasizing new therapeutic techniques such as hypnotherapy are also presented. *'76, 480 pp., 14 il., 34 tables, $21.75*

BECOMING A PSYCHOTHERAPIST *by* **Jacquelin Goldman,** *Univ. of Florida, Gainesville.* This book invites the reader to observe and become involved in many of the major concerns faced in the conduct of psychotherapy. Not only is psychotherapy seen in a general developmental frame of reference, but the reader gains a sense of personal development as he becomes identified with the therapist. Within a developmental frame of reference, the student therapist learns to recognize behavior patterns, to formulate the meaning of behavior, and to understand how his own behavior and that of the patient relate to effective intervention. The Appendix contains a verbatim transcript of an entire therapy session to which references are made within the text. *'76, 140 pp., 2 il., $9.50*

INVOLUNTARY TREATMENT OF THE MENTALLY ILL: The Problem of Autonomy *by* **Michael Alfred Peszke,** *Univ. of Connecticut School of Medicine, Hartford.* This pointed review puts the problem of involuntary treatment of mental illness into historical perspective and looks at it objectively, recognizing that mental illness cannot simply be legislated out of existence. The author suggests that programs designed to meet the needs of the mentally ill be based on the right of each person to his or her own autonomy. Recommendations are also proposed whereby no one in our society is deprived of enlightened and appropriate treatment, while no one is deprived of personal freedom in a thoughtless or arbitrary fashion. *'75, 176 pp., 1 il., $10.75*

Schizophrenia

by Royal Doulton

There is a brooding quality to the figure. She seems lost in her world, cut off from reality, perhaps suspicious, withdrawn and anxious...suggestively schizophrenic in demeanor.

Actual title: 'Romance'. From the Royal Doulton Figurine Collection...one of the many exquisite figures from the master craftsmen of ceramic sculpture, destined to become a collector's item.

Serentil® (mesoridazine)

by Aguilar, *et al.*

"...'hard-core' chronic schizophrenics who have either regressed to a lower level of functioning after initial improvement, or have failed to respond to previous psychotropic medication...can improve significantly [with] Serentil."
Aguilar SJ: Dis Nerv Syst, 36:484, 1975.

"...the onset of mesoridazine's activity can be observed even on the first day of treatment. This rapid onset of action [with the I.M. dosage form] makes mesoridazine valuable in the treatment of psychiatric emergencies."*
Hamid TA and Wertz WJ: Am J Psych 130:689, 1973.

*Because of possible hypotensive effects, parenteral administration should be reserved for bedfast patients or for acute ambulatory cases. Patients should be kept lying down for at least one-half hour after injection.

"...remarkably low incidence of adverse reactions when compared with other phenothiazine compounds."
Serentil Prescribing Information, PDR, 1976.

In prescribing Serentil, observe the same precautions as with other phenothiazines, including awareness of all adverse reactions observed with them. (As with other phenothiazines, patients refractory to previous medications may respond to Serentil.)
Please see next page for a brief summary of the prescribing information, including contraindications and adverse reactions.

Serentil® (mesoridazine) as the besylate

Available in 3 dosage forms: Tablets: 10, 25, 50 and 100 mg. Concentrate: 25 mg/cc. Injectable: 1 cc (25 mg).

—Side effects are usually mild or moderate.

—Except for tremor and rigidity, adverse reactions are usually found in patients receiving high doses early in treatment.

—Low incidence of Parkinson's syndrome.

—Drowsiness and hypotension are the most prevalent side effects encountered.

Indication: Schizophrenia.
Contraindications: Severe central nervous system depression, comatose states and hypersensitivity to the drug.
Warnings: Administer cautiously and increase dosage gradually to patients participating in activities requiring complete mental alertness (e.g., driving). The safety of this drug in pregnancy has not been established; hence it should be given only when the anticipated benefits exceed the possible risk to mother and fetus. Not recommended for use in children under 12 years of age since safe conditions for this use have not been established. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides.
Precautions: Ocular changes have been seen with other phenothiazines but, to date, have not been related to mesoridazine. Because of possible hypotensive effects, reserve parenteral administration for bedfast patients or acute ambulatory cases, and keep patient lying down for at least one-half hour after injection. Leukopenia and/or agranulocytosis have been attributed to phenothiazine therapy. A single case of transient granulocytopenia has been associated with mesoridazine. Patients receiving anticonvulsant medication should be continued on that regimen while receiving mesoridazine to prevent possible convulsive seizures. As with most medications, the dosage of mesoridazine should be adjusted to the needs of the individual and the lowest effective dosage should always be used.
Adverse Reactions: Mesoridazine has demonstrated a remarkably low incidence of adverse reactions compared with other phenothiazine compounds. Drowsiness, Parkinson's syndrome, dizziness, weakness, tremor, restlessness, ataxia, dystonia, rigidity, slurring, akathisia, motoric reactions (opisthotonos). Dry mouth, nausea and vomiting, fainting, stuffy nose, photophobia, constipation and blurred vision have occurred. Inhibition of ejaculation, impotence, enuresis, incontinence. Itching, rash, hypertrophic papillae of the tongue and angioneurotic edema. Hypotension, tachycardia, EKG changes. The following reactions have occurred with

phenothiazines and should be considered: miosis, obstipation, anorexia, paralytic ileus. Erythema, exfoliative dermatitis, contact dermatitis. Agranulocytosis, leukopenia, eosinophilia, thrombocytopenia, anemia, aplastic anemia, pancytopenia. Fever, laryngeal edema, angioneurotic edema, asthma. Jaundice, biliary stasis. Changes in terminal portion of the EKG, including prolongation of the Q-T interval, lowering and inversion of the T wave and appearance of a wave tentatively identified as a bifid T or a U wave have been observed with phenothiazines, including mesoridazine. These appear to be reversible and due to altered repolarization, not myocardial damage. While there is no evidence that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients showing characteristic electrocardiographic changes while taking the drug. While proposed, periodic electrocardiograms would appear to be of questionable value as a predictive device. Hypotension, rarely resulting in cardiac arrest has also been noted. Akathisia, agitation, motor restlessness, dystonic reactions, trismus, torticollis, opisthotonos, oculogyric crises, tremor, muscular rigidity, akinesia. As with all antipsychotics, tardive dyskinesia may appear on long-term therapy or after long-term therapy is discontinued. Risks seem to be greater in elderly patients on high dose therapy, especially females. Discontinue all antipsychotic agents if the symptoms of tardive dyskinesia syndrome appear. (See full prescribing information for description of the symptoms of the tardive dyskinesia syndrome). Menstrual irregularities, altered libido, gynecomastia, lactation, weight gain, edema, false positive pregnancy tests. Retention, incontinence. Hyperpyrexia. behavioral effects suggestive of a paradoxical reaction, including excitement, bizarre dreams, aggravation of psychoses and toxic confusional states. Following long-term therapy, a peculiar skin-eye syndrome marked by progressive pigmentation of areas of the skin or conjunctiva and/or accompanied by discoloration of exposed sclera and cornea; stellate or irregular opacities of anterior lens and cornea. Systemic lupus erythematosus-like syndrome.
How Supplied: *Tablets:* 10 mg., 25 mg., 50 mg. and 100 mg. mesoridazine (as the besylate); packages of 100 and 5000.
Ampuls: 1 cc. [25 mg. mesoridazine (as the besylate).] Inactive ingredients: disodium edetate, U.S.P., 0.5 mg.; sodium chloride, U.S.P., 7.2 mg.; carbon dioxide gas (bone dry) q.s.; water for injection, U.S.P., q.s. to 1 cc.; boxes of 20 and 100. *Concentrate:* 25 mg. mesoridazine (as the besylate) per cc., alcohol, U.S.P., 0.61% by volume. Immediate containers. Amber glass bottles of 4 fl. oz.

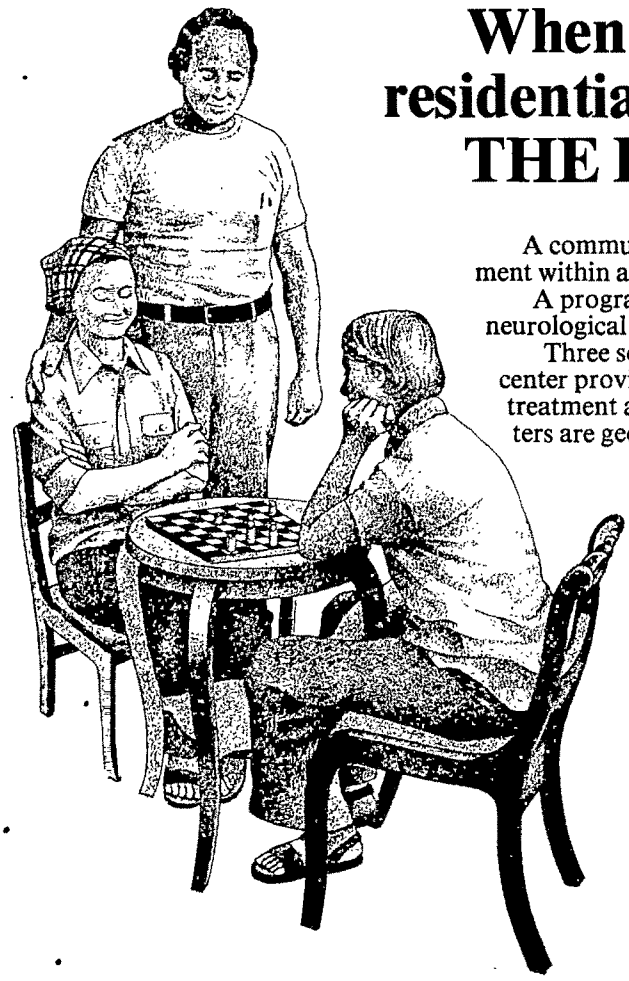
For the patient who needs a UNIQUE CONCEPT in MEDICAL and HOSPITAL CARE.

Las Encinas Hospital

Under complete supervision and direction of its Medical Staff, Las Encinas Hospital offers evaluation and treatment of a patient's total individual needs . . . psychological and physical.

A full time staff of Board certified specialists in Psychiatry, Internal Medicine, Radiology and Psychology, backed by a fully equipped and accredited hospital facility, offers clinical study, diagnosis, and long or short term care. All in a decidedly unhospital-like atmosphere of restful beauty, comfort, privacy and security. Rooms, suites and cottage accommodations available.



FOUNDED IN 1904

Fully Accredited by the JCAH, Approved by A.P.A., Member of All Major Hospital Associations.

Write for our Illustrated Booklet:

When a period of intensive residential treatment is indicated: THE BROWN SCHOOLS

A community within a community to provide individualized treatment within a residential milieu.

A program designed for: psychiatric illness, behavior problems in neurological patients, and rehabilitation of the mentally retarded.

Three separate treatment centers plus a transitional treatment center provide individually prescribed programs of care, education, treatment and training for children, adolescents and adults. The centers are geographically separated to provide the proper residential group, yet near enough to benefit from the combined training and experience of a wide range of staff members.

For information, write: The Director of Admissions, Department C-0, THE BROWN SCHOOLS, P.O. Box 4008, Austin, Texas 78765

NEW FROM
MERCK SHARP & DOHME
FOR THE TREATMENT OF
CLINICALLY SIGNIFICANT
DEPRESSION

TABLETS,

150 mg

Elavil®

(Amitriptyline HCl | MSD)

provides the convenience of
single-tablet h.s. therapy
when control of
symptoms requires
adjustment to the
maximum daily adult
outpatient dosage

Now the 150-mg tablet... another good reason to prescribe ELAVIL® (Amitriptyline HCl | MSD) for clinically significant depression

10 mg

25 mg

50 mg

75 mg

100 mg

150 mg

The other reasons:

- **Efficacy**—ELAVIL is highly effective in the management of clinically significant depression.
- **Six tablet strengths of ELAVIL have been developed** through the years. The introduction of new dosage strengths has helped make ELAVIL even more useful in meeting the dosage needs of depressed patients. They provide improved prescribing flexibility and more convenient regimens.
- **One-tablet-a-day therapy at bedtime is now available with four different dosage strengths.** ELAVIL provides many tablet strengths—50 mg, 75 mg, 100 mg, and 150 mg—for once-a-day therapy in appropriate patients.
- **Tablets are color coded** to help make administration more convenient and accurate.

ELAVIL should not be used during the acute recovery phase following myocardial infarction; in patients hypersensitive to it; in those who have received an MAOI within two weeks; or in children under 12. Patients with cardiovascular disorders should be watched closely. Safe use during pregnancy and lactation has not been established. The drug may impair mental or physical abilities required in the performance of hazardous tasks and may enhance the response to alcohol. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Hospitalize as soon as possible any patient suspected of having taken an overdose.

For a brief summary of prescribing information

MSD
MERCK SHARP & DOHME

TABLETS: 10 mg, 25 mg, 50 mg, 75 mg, 100 mg, and 150 mg
INJECTION: 10 mg per ml

Elavil®
(Amitriptyline HCl | MSD)

a highly effective antidepressant with features to help improve patient compliance

Contraindications: Known hypersensitivity. Should not be given concomitantly with a monoamine oxidase inhibitor since hyperpyretic crises, severe convulsions, and deaths have occurred. When used to replace a monoamine oxidase inhibitor, allow a minimum of 14 days to elapse before initiating therapy with amitriptyline HCl. Initiate dosage of amitriptyline HCl cautiously with gradual increase in dosage until optimum response is achieved. Not recommended during the acute recovery phase following myocardial infarction.

Warnings: May block the antihypertensive action of guanethidine or similarly acting compounds. Should be used with caution in patients with a history of seizures or urinary retention, or with angle-closure glaucoma or increased intraocular pressure; in patients with angle-closure glaucoma, even average doses may precipitate an attack. Patients with cardiovascular disorders should be watched closely; arrhythmias, sinus tachycardia and prolongation of the conduction time have been reported, particularly with high doses; myocardial infarction and stroke have been reported with drugs of this class. Close supervision is required for hyperthyroid patients or those receiving thyroid medication. May impair mental and/or physical abilities required for performance of hazardous tasks, such as operating machinery or driving a motor vehicle. Safe use during pregnancy and actation has not been established; in pregnant patients, nursing mothers, or women who may become pregnant, weigh possible benefits against possible hazards to mother and child. Not recommended for patients under 12 years of age.

Precautions: Schizophrenic patients may develop increased symptoms of psychosis; patients with paranoid symptomatology may have an exaggeration of such symptoms; manic depressive patients may experience a shift to the manic phase. In these circumstances, the dose of amitriptyline HCl may be reduced or a major tranquilizer, such as perphenazine, may be administered concurrently.

When given with anticholinergic agents or sympathomimetic drugs, including epinephrine combined with local anesthetics, close supervision and careful adjustment of dosages are required; paralytic ileus may occur in patients taking tricyclic antidepressants in combination with anticholinergic-type drugs. Use cautiously in patients receiving large doses of ethchlorvynol, since transient delirium has been reported on concurrent administration. May enhance the response to alcohol and the effects of barbiturates and other CNS depressants. The possibility of suicide in depressed patients remains until significant remission occurs. Potentially suicidal patients should not have access to large quantities of this drug. Prescriptions should be written for the smallest amount feasible. Concurrent electroshock therapy may increase the hazards associated with such therapy; such treatment should be limited to patients for whom it is essential. When possible, discontinue the drug several days before elective surgery. Both elevation and lowering of blood sugar levels have been reported. Use with caution in patients with impaired liver function.

Adverse Reactions: *Note:* Included in this listing are a few adverse reactions not reported with this specific drug. However, pharmacological similarities among the tricyclic antidepressant drugs require that each reaction be considered when amitriptyline is administered. *Cardiovascular:* Hypotension, hypertension, tachycardia, palpitation, myocardial infarction, arrhythmias, heart block, stroke. *CNS and Neuromuscular:* Confusional states; disturbed concentration; disorientation; delusions; hallucinations; excitement; anxiety; restlessness; insomnia; nightmares; numbness, tingling, and paresthesias of the extremities; peripheral neuropathy; incoordination; ataxia; tremors; seizures; alteration in EEG patterns; extrapyramidal symptoms; tinnitus; syndrome of inappropriate ADH (antidiuretic hormone) secretion. *Anticholinergic:* Dry mouth, blurred vision, disturbance of accommodation, increased intraocular pressure, constipation, paralytic ileus, urinary retention, dilatation of urinary tract. *Allergic:* Skin rash, urticaria, photosensitization, edema of face and tongue. *Hematologic:* Bone marrow depression including agranulocytosis, leukopenia, eosinophilia, purpura, thrombocytopenia. *Gastrointestinal:* Nausea, epigastric distress, vomiting, anorexia, stomatitis, peculiar taste, diarrhea, parotid swelling, black tongue, rarely hepatitis (including altered liver function and jaundice). *Endocrine:* Testicular swelling and gynecomastia in the male, breast enlargement and galactorrhea in the female, increased or decreased libido, elevation and lowering of blood sugar levels. *Other:* Dizziness, weakness, fatigue, headache, weight gain or loss, increased perspiration, urinary frequency, mydriasis, drowsiness, alopecia. *Withdrawal Symptoms:* Abrupt cessation of treatment after prolonged administration may produce nausea, headache, and malaise; these are not indicative of addiction.

Overdosage: Hospitalize as soon as possible all patients suspected of having taken an overdose. Treatment is symptomatic and supportive. In addition, the intravenous administration of 1 to 3 mg physostigmine salicylate is reported to reverse the symptoms of tricyclic antidepressant poisoning. Because physostigmine is rapidly metabolized, the dosage should be repeated as required, particularly if life-threatening signs such as arrhythmias, convulsions, and deep coma recur or persist after the initial dosage of physostigmine.

How Supplied: Tablets containing 10 mg and 25 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100, 1000, and 5000; tablets containing 50 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100 and 1000; tablets containing 75 mg and 100 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 100; tablets containing 150 mg amitriptyline HCl, in single-unit packages of 100 and bottles of 30 and 100; for intramuscular use, in 10-ml vials containing per ml: 10 mg amitriptyline HCl, 44 mg dextrose, 1.5 mg methylparaben and 0.2 mg propylparaben as preservatives, and water for injection q.s. 1 ml.

addendum

MSD
MERCK SHARP & DOHME

To further simplify once-daily therapy for many depressed patients

Tablets

Elavil®
(Amitriptyline HCl | MSD)

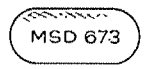
ONE TABLET, ONCE DAILY

—an appropriate way to prescribe for many depressed adult outpatients. Because of its simplicity, this regimen helps improve patient compliance. Of course, ELAVIL may also be prescribed in divided daily doses.

ONCE-DAILY DOSAGE SCHEDULE FOR ADULT OUTPATIENTS:

A single 75-mg tablet
Usual starting dosage

A single 100-mg tablet
Maximum starting dosage



A single 50-mg tablet
Minimum starting dosage

Dosage may be increased by 25 or 50 mg as necessary until a total of 150 mg per day is reached.

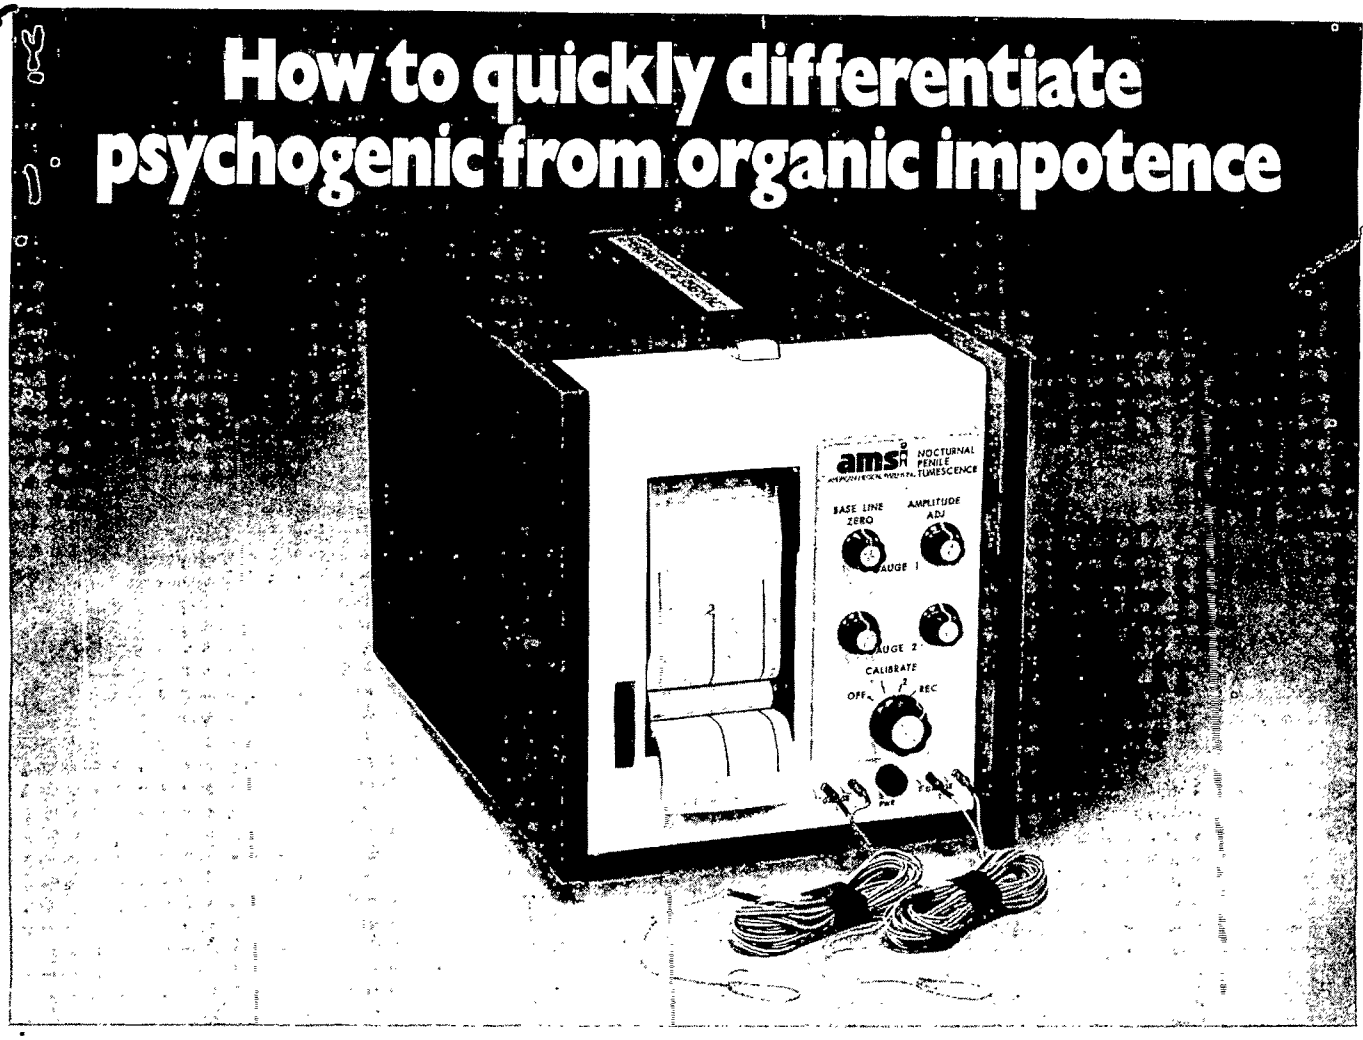
A single 150-mg tablet
Maximum daily dosage

ELAVIL MAY ALSO BE PRESCRIBED IN DIVIDED DAILY DOSES

The 25-mg tablet

This strength may prove useful when therapy is initiated with divided daily doses in adult outpatients. Starting dosage is usually 75 mg daily. If necessary, this dosage may be increased gradually to a total of 150 mg a day. Increases are made preferably in the late afternoon or bedtime dose.

The 10-mg tablet



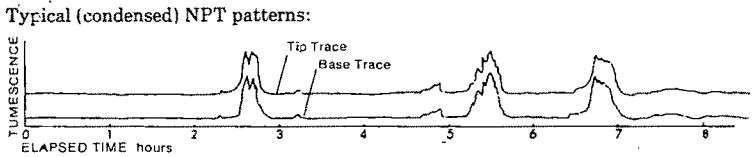
This strength may prove useful for patients who require lower doses, e.g., adolescent and elderly patients. For these patients who can not tolerate higher doses, 10 mg three times a day with 20 mg at bedtime may be satisfactory.

A sedative effect may be apparent before the antidepressant effect of ELAVIL is noted. An adequate therapeutic effect may take as long as 30 days to develop.

NOTE: The usual maintenance dosage of ELAVIL is 50 to 100 mg per day which may be given in a single dose preferably at bedtime. In some patients 40 mg per day is sufficient. This drug is not recommended for patients under 12 years of age.

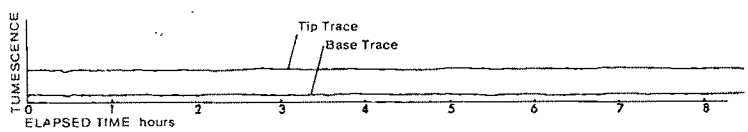
How to quickly differentiate psychogenic from organic impotence

The American Medical Systems Nocturnal Penile Tumescence Monitor (Model N-7600) has been developed to aid in the diagnosis and study of male erectile impotence.



Test results from the monitor help the physician to clearly and objectively differentiate pyschogenic from organic cases of impotence. And in turn to determine the appropriate course of psycho or medical therapy.

Utilizing two mercury strain gauges that are positioned at the base and at the tip of the penis, the NPT Monitor measures minute variations in penile size during the Rapid Eye Movement stages of sleep. The test results are amplified and recorded on a strip chart mechanism as a permanent patient record for subsequent evaluation.



This rugged, lightweight monitor is easy to operate, allowing NPT testing in the hospital, sleep laboratory, physician's office or by the patient in his home.

For further information or scientific references, mail the coupon today or call collect: 612-927-4211.

Typical (condensed) NPT patterns:

This Tracing indicates significant tumescence activity. Organic impotence can be ruled out.

This Tracing has no tumescence activity strongly indicating that impotence is of an organic nature.

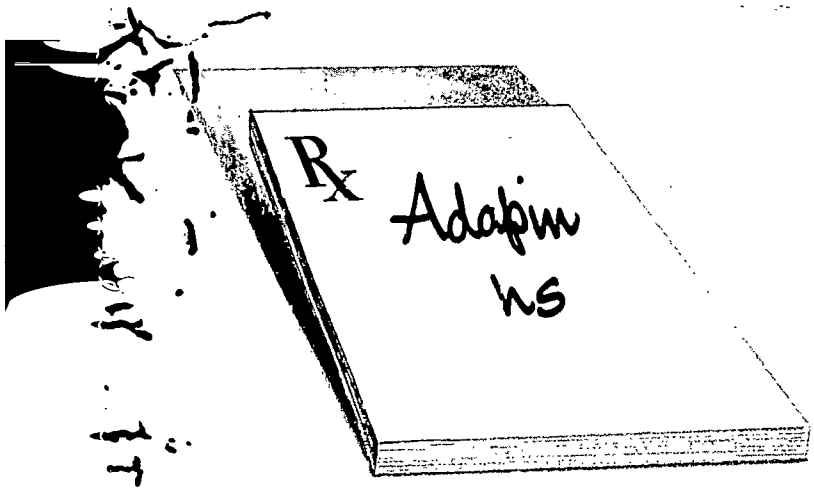
ADAPIN®
(Doxepin HCl)
Capsules, 10 mg., 25 mg., 50 mg.

And the Management of Disturbed Sleep Patterns in Anxiety/Depression

Disturbed sleep patterns are a familiar component of the symptom complex seen in patients with anxiety and/or depression.

One study[1] has shown that doxepin [Adapin] is helpful in providing symptomatic relief of sleep disturbances associated with anxiety and depression, "allowing patients to fall asleep more rapidly and feel more rested upon awakening."

Another study[2] points out that doxepin [Adapin] given "at bedtime to outpatients with mixed anxiety and depression will yield as much improvement as can be obtained by giving the drug three times a day."



So, a single dose of Adapin, given at bedtime can often help promote a restful night's sleep for patients with mixed anxiety and depression. Other clinical benefits include:

- rapid antianxiety effect
- distinct clinical brightening of mood—usually within three to four weeks
- low incidence of side effects
- suitability for long-term usage

ADAPIN®

(Doxepin HCl)

Prescribing information:

DESCRIPTION

Adapin (doxepin HCl) is an isomeric mixture of N, N-dimethyl-dibenz(b,e) oxepin- $\Delta^{11(6H)}$, γ propylamine hydrochloride.

ACTIONS

Adapin has a variety of pharmacological actions with its predominant action on the central nervous system. While its mechanism of action is not known, studies have demonstrated that it is neither a monoamine oxidase inhibitor nor a primary stimulant of the central nervous system.

INDICATIONS

In controlled clinical evaluations, **Adapin** has shown marked antianxiety and significant antidepressant effects. **Adapin** has been found to be well tolerated even in elderly patients.

Adapin is indicated for the treatment of patients with:

1. Psychoneurotic anxiety and/or depressive reactions.
2. Mixed symptoms of anxiety and depression.
3. Anxiety and/or depression associated with alcoholism.
4. Anxiety associated with organic disease.
5. Psychotic depressive disorders including involutional depression and manic-depressive reactions.

Target symptoms of psychoneurosis that respond particularly well to **Adapin** include: anxiety, tension, depression, somatic symptoms and concerns, insomnia, guilt, lack of energy, fear, apprehension and worry.

Because **Adapin** provides antidepressant as well as antianxiety effects, it is of particular value in patients in whom anxiety masks depression. Patients who have not responded to other antianxiety or antidepressant drugs may benefit from **Adapin.**

In a large series of patients systematically observed for withdrawal symptoms, none were reported—a finding which is consistent with the virtual absence of euphoria as a side effect and the lack of addictive potential characteristic of this type of chemical compound.

CONTRAINDICATIONS

Because **Adapin** has an anticholinergic effect, it is contraindicated in patients with glaucoma or a tendency toward urinary retention.

Use of **Adapin** is contraindicated in patients who have been found hypersensitive to it.

WARNINGS

Usage in Pregnancy—Adapin has not been evaluated in pregnant patients. Therefore, it should not be used during pregnancy unless, in the judgment of the physician, it is essential to the welfare of the patient.

In animal reproduction studies of **Adapin (doxepin hydrochloride),** gross ar microscopic examination of the offspring gave no evidence of drug-related teratogenic effect. Following doses of up to 25 mg./kg./day for 8 to 9 month no changes were observed in the number of live births, litter size, or lactatic A decreased rate of conception was observed when male rats were given 25 mg./kg./day for prolonged periods—an effect which has occurred with other psychotropic drugs and has been attributed to drug effect on the centr and/or autonomic nervous systems.

Usage in Children—The use of **Adapin** in children under 12 years of age is r recommended, because safe conditions for its use have not been establishe

MAO Inhibitors—Serious side effects and even death have been reported following the concomitant use of certain drugs with MAO inhibitors. Therefo MAO inhibitors should be discontinued at least two weeks prior to the cauti initiation of therapy with **Adapin.** The exact length of time may vary and is dependent upon the particular MAO inhibitor being used, the length of time has been administered, and the dosage involved.

PRECAUTIONS

Drowsiness may occur with **Adapin;** therefore, patients should be warned of its possible occurrence and cautioned against driving a motor vehicle or operating hazardous machinery while taking the drug.

Patients should also be cautioned that the effects of alcoholic beverages ma be increased.

Since suicide is an inherent risk in depressed patients and remains a risk through the initial phases of improvement, depressed patient should be closely supervised.

Although **Adapin** has shown effective tranquilizing activity, the possibility of activating or unmasking latent psychotic symptoms should be kept in mind.

Compounds structurally related to **Adapin** can block the effects of guanethidine and similarly acting compounds. However, at the usual clinica dosages, 75 mg. to 150 mg. per day, **Adapin** has been given concomitantly with guanethidine without blocking its antihypertensive effect. But at dosag of 300 mg. per day or higher, **Adapin** has exerted a significant blocking effec

Adapin, like other structurally related psychotropic drugs, potentiates norepinephrine response in animals. But this effect has not been observed v **Adapin** in humans, which is in accord with the low incidence of tachycardia reported clinically.

ADVERSE REACTIONS

Anticholinergic Effects: Dry mouth, blurred vision and constipation have be reported. These are usually mild, and often subside as therapy is continued or dosage reduced.

Central Nervous System Effects: Drowsiness has been observed. It usually occurs early in the course of therapy and tends to subside as therapy continues. (See Dosage and Administration section.)

Cardiovascular Effects: Tachycardia and hypotension have been reported infrequently.

Other infrequently reported adverse effects include extrapyramidal symptom gastrointestinal reactions, secretory effects (such as increased sweating), weakness, dizziness, fatigue, weight gain, edema, paresthesias, flushing, chills, tinnitus, photophobia, decreased libido, rash, and pruritus.

DOSAGE AND ADMINISTRATION

In most patients with mild to moderate anxiety and/or depression: 10 mg. to 25 mg. t.i.d. to start. A starting dosage of 10 mg. t.i.d. for a period of four days may reduce the initial drowsiness experienced by some patients and may be tried in cases where drowsiness is clinically undesirable. Decre or increase the dosage at appropriate intervals according to individual response. Usual optimum dosage is 75 mg. to 150 mg. per day.

In some patients with mild symptomatology or emotional symptoms accompanying organic disease, dosage as low as 25 mg. to 50 mg. per day has provided effective control.

In more severe anxiety and/or depression: 50 mg. t.i.d. may be required to start—if necessary, gradually increase to 300 mg. per day. Additional effectiveness is rarely obtained by exceeding 300 mg. per day.

Although optimal antidepressant response may not be evident for two to three weeks, antianxiety activity is rapidly apparent.

OVERDOSAGE

Symptoms—An increase of any of the reported adverse reactions, primarily excessive sedation and anticholinergic effects such as blurred vision and dr mouth. Other effects may be: pronounced tachycardia, hypotension and extrapyramidal symptoms.

Treatment—Essentially symptomatic; supportive therapy in the case of hypotension and excessive sedation.

HOW SUPPLIED

Each capsule contains doxepin, as the hydrochloride, 10 mg. (NDC 0018-0356), 25 mg. (NDC 0018-0357), and 50 mg. (NDC 0018-0358) capsules in bottles of 100 and 1000.

AN EQUAL OPPORTUNITY EMPLOYER GROW WITH US AT HUTCHINGS

THE UNIVERSITY OF VERMONT COLLEGE OF MEDICINE

Department of Psychiatry

offers

a 4 year residency training program in psychiatry to medical graduates. The first year includes 6 months medicine/neurology and 6 months psychiatry at the Champlain Valley Physicians Hospital in Plattsburgh, New York. The second year, available to those who have completed the first postgraduate year elsewhere, features an inpatient experience at the Medical Center Hospital of Vermont in Burlington and a rotation of three months in the Crisis Intervention Service. Also during this year the resident will begin longterm outpatient psychotherapy under intensive supervision. The third year emphasizes ambulatory experiences, including child and adolescent psychiatry. Rotations in consultation-liaison, community mental health and other selective experiences complete the program.

Child psychiatry and consultation-liaison fellowships are available.

For further information and application materials write: Andrew Siegel, M.D., Director of Residency Training, UVM Department of Psychiatry, Medical Alumni Building, Burlington, VT, 05401.

THE AMERICAN JOURNAL OF PSYCHIATRY

NOW, your journals can become an attractive permanent part of your professional library. These famous Jesse Jones volume files, especially designed to keep your copies orderly, readily accessible for future reference—guard against soiling, tearing, wear or misplacement of copies. These durable files will support 150 lbs. Looks and feels like leather and is washable. The 23-carat gold lettering makes it a fit companion for the most costly binding.

Reasonably priced, too. Only $4.25, 3 for $12.00, 6 for $22.00 POSTPAID U. S. A. ORDERS ONLY. Satisfaction unconditionally guaranteed or your money back.

Department JP9—Philadelphia 41, Pa. 19141

UNIVERSITY OF OTAGO

Faculty of Medicine

CHRISTCHURCH CLINICAL SCHOOL

Christchurch — New Zealand

LECTURER OR SENIOR LECTURER IN PSYCHOLOGICAL MEDICINE

Applications are invited from medical graduates for the appointment of Lecturer or Senior Lecturer in Psychological Medicine in the recently established Christchurch Clinical School.

Duties will include undergraduate and postgraduate teaching, participation in patient care, and research.

Salary: Lecturer: $NZ11,407-$NZ15,932 per annum with a bar at $NZ13,309 per annum

Senior Lecturer: $NZ16,369-$NZ18,730 per annum

(Note: $NZ100 equals approximately £55 sterling; $US100)

Information about the Department may be obtained from the Professor of Psychological Medicine, The Christchurch Clinical School, Christchurch, New Zealand.

Further particulars are available from the Secretary-General, Association of Commonwealth Universities, (Appointments), 36 Gordon Square, London WC1H OPF, or from the undersigned.

Applications, quoting reference A.76/62, close in London, and with the undersigned in New Zealand on 31 December 1976.

D. W. GIRVAN

REMOVE THE MASK OF SCHIZOPHRENIC SYMPTOMS

'STELAZINE' PROVIDES EFFECTIVE CONTROL OF HALLUCINATIONS, DELUSIONS, ANXIETY AND OTHER SCHIZOPHRENIC SYMPTOMS IN A WIDE RANGE OF PATIENTS.

FROM THE WITHDRAWN AND APATHETIC TO THE ANXIOUS AND OVERACTIVE, 'STELAZINE' HELPS RETURN THE PSYCHOTIC PATIENT TO REALITY AND CAN FACILITATE THERAPEUTIC CONTACT AND RAPPORT.

- EFFECTIVELY CONTROLS PSYCHOTIC SYMPTOMS
- SELDOM CAUSES EXCESSIVE SEDATION
- CONVENIENT B.I.D. DOSAGE

Before prescribing, see complete prescribing information in SK&F literature or *PDR*. The following is a brief summary.

Indications
Based on a review of this drug by the National Academy of Sciences—National Research Council and/or other information, FDA has classified the indications as follows:

Effective: For the management of the manifestations of psychotic disorders.

Possibly effective: To control excessive anxiety, tension and agitation as seen in neuroses or associated with somatic conditions.

'Stelazine' has not been shown effective in the management of behavioral complications in patients with mental retardation.

Final classification of the less-than-effective indications requires further investigation.

Contraindications: Comatose or greatly depressed states due to C.N.S. depressants; blood dyscrasias; bone marrow depression; liver damage.

Warnings: Caution patients about activities requiring alertness (e.g., operating vehicles or machinery), especially during the first few days' therapy.

Use in pregnancy only when necessary for patient's welfare.

Precautions: Use cautiously in angina. Avoid high doses and parenteral administration when cardiovascular system is impaired. Antiemetic effect may mask signs of toxic drug overdosage or physical disorders. Additive effect is possible with other C.N.S. depressants. Prolonged administration of high doses may result in cumulative effects with severe C.N.S. or vasomotor symptoms. If retinal changes occur, discontinue drug. Agranulocytosis, thrombocytopenia, pancytopenia, anemia, cholestatic jaundice, liver damage have been reported.

Adverse Reactions: Drowsiness, dizziness, skin reactions, rash, dry mouth, insomnia, amenorrhea, fatigue, muscular weakness, anorexia, lactation, blurred vision. Neuromuscular (extrapyramidal) reactions: motor restlessness, dystonias, pseudo-parkinsonism, persistent tardive dyskinesia.

Other adverse reactions reported with Stelazine (trifluoperazine HCl, SK&F) or other phenothiazines: Some adverse effects are more frequent or intense in specific disorders (e.g., mitral insufficiency or pheochromocytoma).

Grand mal convulsions; altered cerebrospinal fluid proteins; cerebral edema; prolongation and intensification of the action of C.N.S. depressants, atropine, heat, and organophosphorus insecticides; nasal congestion, headache, nausea, constipation, obstipation, adynamic ileus, inhibition of ejaculation; reactivation of psychotic processes, catatonic-like states; hypotension (sometimes fatal); cardiac arrest; leukopenia, eosinophilia, pancytopenia, agranulocytosis, thrombocytopenic purpura; jaundice, biliary stasis; menstrual irregularities, galactorrhea, gynecomastia, false positive pregnancy tests; photosensitivity, itching, erythema, urticaria, eczema up to exfoliative dermatitis; asthma, laryngeal edema, angioneurotic edema, anaphylactoid reactions; peripheral edema; reversed epinephrine effect; hyperpyrexia; a systemic lupus erythematosus-like syndrome; pigmentary retinopathy; with prolonged administration of substantial doses, skin pigmentation, epithelial keratopathy, and lenticular and corneal deposits. EKG changes have been reported, but relationship to myocardial damage is not confirmed. Discontinue long-term, high-dose therapy gradually. NOTE: Sudden death in patients taking phenothiazines (apparently due to cardiac arrest or asphyxia due to failure of cough reflex) has been reported, but no causal relationship has been established.

Supplied: Tablets, 1 mg., 2 mg., 5 mg. and 10 mg., in bottles of 100; in Single Unit Packages of 100 (intended for institutional use only); Injection, 2 mg./ml.; and Concentrate (intended for institutional use only) 10 mg./ml.

New program for more than symptomatic control of the schizophrenic...

new from Dome Laboratories: a dual approach to help the schizophrenic adjust to a more normal life

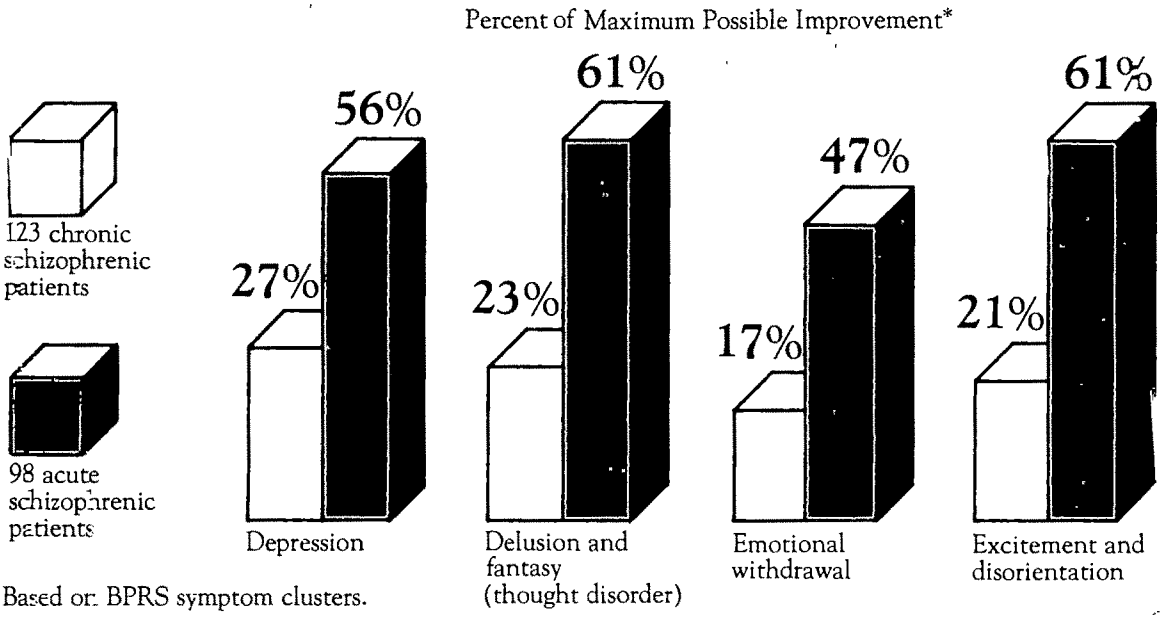
first...

symptomatic help for the schizophrenic

Daxolin®
(loxapine succinate)

extensively investigated clinically

Loxapine succinate [Daxolin] has been studied clinically in both chronic and acute schizophrenic patients.[1]



evaluated by psychiatrists—BPRS (Brief Psychiatric Rating Scale), CGI (Clinical Global Impression)

evaluated by psychiatric nurses—NOSIE (Nurse's Observation Scale for Inpatient Evaluation)

compared with various other agents including chlorpromazine, trifluoperazine, thiothixene, as well as placebo—from 11 published, controlled/double-blind studies involving 441 patients[1]

helps control symptoms of acute and chronic schizophrenia

Evaluation (by BPRS) of symptomatic response in 221 chronic and acute schizophrenic patients[1]

*Based on BPRS symptom clusters.

- ☐ significant improvement noted in behavior patterns, severity of symptoms significantly reduced
- ☐ helps control symptoms in responsive patients
- ☐ dosage strengths to meet individual needs
- ☐ manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently.†

†See "Adverse Reactions" and "Actions" sections in the prescribing information on last page.

and...

second...
help for those close to the schizophrenic

EMP (EMPATHIC) COMMUNICATIONS

The symptoms of schizophrenia can be bizarre and puzzling—especially to family and others in close contact with the patient. To help them understand the disease, and thus be more helpful to the patient, Dome Laboratories offers *EMP* (Empathic) *Communications,* a comprehensive new education program developed especially for lay readers.

By providing authoritative, easy-to-understand booklets, this program encourages family and friends to cooperate in the patient's adjustment to therapy and rehabilitation.

...and for your information

PSYCHIATRIC INTERFACES

A new and ongoing publication of firsthand information that deals with current psychiatric trends and offers opinions on mental-health care from prominent psychiatrists.

EMP (EMPATHIC) COMMUNICATIONS
for the patient's family

The first in a series of booklets that answers a number of worrisome questions on how to cope with schizophrenia.

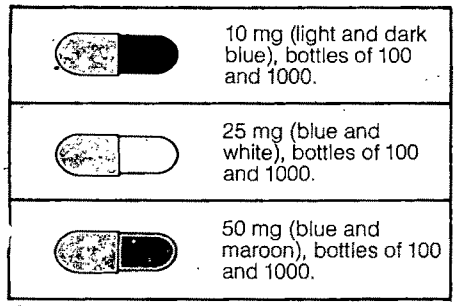
Other booklets offer specific information for *individual* members of the family and others in close contact with the patient, such as the employer, co-workers, paramedical personnel.

now...more than symptomatic control for the schizophrenic

EMP COMMUNICATIONS—an impressive educational program

PSYCHIATRIC INTERFACES—an outstanding information service

and



Daxolin®
(loxapine succinate

a promising neuroleptic agent for symptomatic control of schizophrenia

See next page for prescribing inform

Daxolin® (loxapine succinate)

individualized dosage strengths to meet the varying needs of the schizophrenic

10 mg (light and dark blue), bottles of 100 and 1000.

25 mg (blue and white), bottles of 100 and 1000.

50 mg (blue and maroon), bottles of 100 and 1000.

Description: DAXOLIN (loxapine succinate), a dibenzoxazepine compound, represents a new subclass of tricyclic antipsychotic agent, chemically distinct from the thioxanthenes, butyrophenones, and phenothiazines. Chemically, it is 2-chloro-11-(4-methyl-1-piperazinyl) dibenz[b,f][1,4] oxazepine. It is present in capsules as the succinate salt. Each 1.36 mg of loxapine succinate is equivalent to 1 mg of loxapine.

Actions: Pharmacologically, loxapine is a tranquilizer for which the exact mode of action has not been established. However, changes in the level of excitability of subcortical inhibitory areas have been observed in several animal species in association with such manifestations of tranquilization as calming effects and suppression of aggressive behavior.

In normal human volunteers, signs of sedation were seen within 20 to 30 minutes after administration, were most pronounced within 1½ to 3 hours, and lasted through 12 hours. Similar onset and duration of primary pharmacologic effect was seen in animals.

Absorption of loxapine following oral or parenteral administration is virtually complete. The drug is removed rapidly from the plasma and distributed in tissues. Animal studies suggest an initial preferential distribution in lungs, brain, spleen, heart, and kidney. Loxapine is metabolized extensively and excreted mainly in the first 24 hours. Metabolites are excreted in the urine in the form of conjugates but are unconjugated in the feces.

...have not been performed in ...is not recommended for use ...16.

...ilizers, may impair mental ...ecially during the first few ...mbulatory patients should ...uiring alertness (eg, oper... ...d about concomitant use ...ssants.

Precautions: DAXOLIN should be used with extreme caution in patients with a history of convulsive disorders since it lowers the convulsive threshold. Seizures have been reported in epileptic patients receiving DAXOLIN at antipsychotic dose levels, and may occur even with maintenance of routine anticonvulsant drug therapy.

Loxapine has an antiemetic effect in animals. Since this effect also may occur in man, loxapine may mask signs of overdosage of toxic drugs and obscure conditions such as intestinal obstruction and brain tumor.

DAXOLIN should be used with caution in patients with cardiovascular disease. Increased pulse rates have been reported in the majority of patients receiving antipsychotic doses; and transient hypotension has been reported. In the presence of severe hypotension requiring vasopressor therapy, the preferred drugs may be norepinephrine or angiotensin. Usual doses of epinephrine may be ineffective because of inhibition of its vasopressor effect by loxapine.

The possibility of ocular toxicity from loxapine cannot be excluded at this time. Therefore, careful observation should be made for pigmentary retinopathy and lenticular pigmentation since these have been observed in some patients receiving certain other antipsychotic drugs for prolonged periods.

Because of possible anticholinergic action, the drug should be used cautiously in patients with glaucoma or a tendency to urinary retention, particularly with concomitant administration of anticholinergic-type antiparkinsonian medication.

Adverse Reactions: *CNS Effects:* Manifestations of adverse effects on the central nervous system, other than extrapyramidal effects, have been seen infrequently. Drowsiness, usually mild, may occur at the beginning of therapy or when dosage is increased. It usually subsides with continued DAXOLIN (loxapine succinate) therapy. The incidence of sedation has been less than that of certain aliphatic phenothiazines and slightly more than the piperazine phenothiazines. Dizziness, faintness, staggering gait, muscle twitching, weakness, and confusional states have been reported.

Extrapyramidal Reactions—Neuromuscular (extrapyramidal) reactions during the administration of DAXOLIN have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved parkinsonism-like symptoms such as tremor, rigidity, excessive salivation, and masked facies. Akathisia (motor restlessness) also has been reported relatively frequently. These symptoms are usually not severe and can be controlled by reduction of DAXOLIN dosage or by administration of antiparkinsonian drugs in usual dosage. Dystonic and dyskinetic reactions have occurred less frequently, but may be more severe. Dystonias include spasms of muscles of the neck and face, tongue protrusion, and oculogyric movement. Dyskinetic reaction has been described in the form of choreoathetoid movements. These reactions sometimes require reduction or temporary withdrawal of DAXOLIN dosage in addition to appropriate counteractive drugs.

Persistent Tardive Dyskinesia—In keeping with the action of all antipsychotic agents, tardive dyskinesia may appear in some patients on long-term therapy or may appear after drug therapy has been discontinued. The risk appears to be greater in elderly patients—especially females—on high-dose therapy. The symptoms are persistent and, in some patients, appear to be irreversible. The syndrome is characterized by rhythmical involuntary movement of the tongue, face, mouth, or jaw (eg, protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of the extremities.

There is no known effective treatment for tardive dyskinesia; antiparkinsonian agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, the syndrome may be masked. It has been suggested that fine vermicular movements of the tongue may be an early sign of the syndrome; if the medication is stopped at that time the syndrome may not develop.

Cardiovascular Effects: Tachycardia, hypotension, hypertension, light-headedness, and syncope have been reported. A few cases of ECG changes similar to those seen with phenothiazines have been reported. It is not known whether these were related to loxapine administration.

Skin Effects: Dermatitis, edema (puffiness of face), pruritus, and seborrhea have been reported with loxapine. The possibility of photosensitivity and/or photoxicity occurring has not been excluded; skin rashes of uncertain etiology have been observed in a few patients during hot summer months.

Endocrine Effects: No endocrine abnormalities have been reported.

Anticholinergic Effects: Dry mouth, nasal congestion, constipation, and blurred vision have occurred; these are more likely to occur with concomitant use of antiparkinsonian agents.

Other Adverse Reactions: Nausea, vomiting, weight gain, weight loss, dyspnea, ptosis, hyperpyrexia, flushed facies, headache, paresthesia, and polydipsia have been reported in some patients.

Dosage and Administration: DAXOLIN (loxapine succinate) is administered orally, usually in divided doses, two to four times a day. Daily dosage (in terms of base equivalents) should be adjusted to the individual patient's needs as assessed by the severity of symptoms and previous history of response to antipsychotic drugs. Initial dosage of 10 mg twice daily is recommended although, in severely disturbed patients, initial dosage up to a total of 50 mg daily may be desirable. Dosage should then be increased fairly rapidly over the first seven to ten days until there is effective control of psychotic symptoms. The usual therapeutic and maintenance range is 60 mg to 100 mg daily. However, as with other antipsychotic drugs, some patients respond to lower dosage and others require higher dosage for optimal benefit. Daily dosage higher than 250 mg is not recommended. For maintenance therapy, dosage should be reduced to the lowest level compatible with symptom control; many patients have been maintained satisfactorily at dosages in the range of 20 mg to 60 mg daily.

How Supplied: DAXOLIN™ (loxapine succinate) is supplied in the following base-equivalent strengths:
CAPSULES Hard Shell Printed "DOME"
10 mg—Light and Dark Blue; bottles of 100 and 1000.
25 mg—Blue and White; bottles of 100 and 1000.
50 mg—Blue and Maroon; bottles of 100 and 1000.

Manufactured for Dome Laboratories by Lederle Laboratories Division, American Cyanamid Company, Pearl River, N.Y.

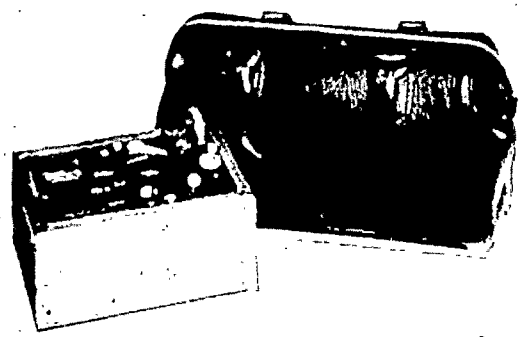
MORE THAN 30 YEARS...

have proven the dependability and effectiveness of REITER ELECTROSTIMULATORS in psychiatry! Research and constant improvements to meet the standards of improved techniques have kept Reiter instruments

THE WORLD'S MOST ACCEPTED ELECTROSTIMULATORS

The Two Popular Models— **PORTABLE FOR OFFICE AND CLINIC**



The Reiter MODEL SOS—THE ONE INSTRUMENT FOR ALL ESTABLISHED TECHNIQUES, provides the fullest range of safest therapies. For painless, gentle stimulation of the conscious patient to relieve anxiety, depression, etc. Maximum safety, no additives—patient conscious and cooperating with therapy.

The SOS has also been used universally for Convulsive Therapy, Non-Convulsive Therapies, Electro-Sleep Therapy, Focal Treatment, Mono-Polar Treatment, Barbiturate Coma (and other respiratory problems), Mild Sedac, Deep Sedac Therapy, Pre-Convulsive Sedac, Post-Convulsive Sedac, Neurological Conditions, and Measurement Procedures.

Available with this redesigned model, on request, the following special-purpose electrodes —a Multi-Polar "Collar" type for Sleep Therapy, a "Horseshoe" assembly for quicker, surer application with one hand at last moment before ECT treatment, and a "Unilateral" type assembly.

Also built-in on request, an **automatic switch** for quicker build up to therapeutic ranges of Sedac.

SPECIAL MODEL SOS available without unidirectional convulsive current.

The Reiter Compact MOL-AC II—The smallest, lightest, least expensive and most reliable, clinically proven A.C. shock therapy instrument. Less confusion than from similar A.C. equipment. Now available with redesigned, improved panel. This compact instrument is only 3 x 5 inches, weighs but 3 lbs., yet provides full positive control of glisando effect over entire voltage range, as well as a positive manual control of time. There are NO complicated settings of dials, NO waiting for resetting of time devices, no warm-up delays.

An officially approved, extremely durable instrument which has earned world-wide professional acceptance, the MOL-AC II is economically priced with a fine, genuine leather physician's bag included.

Other Models Still Available: The CW47, original therapeutic cerebral stimulator with only 3 of the 9 treatment current selections available on Model SOS.
